Minerals Yearbook

1974

Volume I

METALS, MINERALS, AND FUELS

Prepared by staff of the

BUREAU OF MINES

UNITED STATES DEPARTMENT OF THE INTERIOR ● Thomas S. Kleppe, Secretary

BUREAU OF MINES ● Thomas V. Falkie, Director

As the Nation's principal conservation agency, the Department of the Interior has basic responsibilities to protect and conserve our land and water, energy and minerals, fish and wildlife, and park and recreation areas, and for the wise use of all those resources. The Department also has a major responsibility for American Indian reservation communities and for the people who live in Island Territories under U.S. administration.

Foreword

The Federal Government, through the medium of the Minerals Yearbook or its predecessor volumes, has for 92 years reported annually on mineral industry activities. This edition of the Minerals Yearbook presents the record on worldwide mineral industry performance during 1974. In addition to statistics, the volumes provide background information to help in interpreting the year's developments. The content of the individual volumes is as follows:

Volume I, Metals, Minerals, and Fuels, contains chapters on virtually all metallic, nonmetallic, and mineral fuel commodities important to the domestic economy. In addition, it includes a general review chapter on the mineral industries, a statistical summary, and a chapter on mining and quarrying trends.

Volume II, Area Reports: Domestic, contains chapters on the mineral industry of each of the 50 States, the U.S. island possessions in the Pacific Ocean and the Caribbean Sea, the Commonwealth of Puerto Rico, and the Canal Zone. This volume also has a statistical summary, identical to that in Volume I.

Volume III, Area Reports: International, contains the latest available mineral data on more than 130 foreign countries and discusses the importance of minerals to the economies of these nations. A separate chapter reviews minerals in general and their relationships to the world economy.

The Bureau of Mines continually strives to improve the value of the Yearbook for its users. Therefore, the constructive comments and suggestions of readers will be welcomed.

THOMAS V. FALKIE, *Director*.

Acknowledgments

Volume I, Metals, Minerals, and Fuels of the Minerals Yearbook summarizes the significant data pertaining to mineral commodities obtained as a result of the mineral information gathering activities of the Associate Directorate—Mineral and Materials Supply Demand Analysis.

The collection, compilation, and analysis of data on the domestic minerals and mineral fuel industries were performed by the staffs of the Divisions of Ferrous Metals, Nonferrous Metals, Nonmetallic Minerals, Assistant Directorate Metals, Minerals and Materials; the Divisions of Coal, Petroleum and Natural Gas, and Fuels Data, Assistant Directorate, Fuels; and the Division of Economic Analysis, Assistant Directorate, Interindustry and Economic Analysis. Statistical data were compiled from information supplied by mineral producers, processors, and users in response to production and consumption canvasses, and their voluntary response is gratefully acknowledged. The information obtained from individual firms by means of confidential surveys has been grouped to provide statistical aggregates. Data on individual firms are presented only if available from published or other nonconfidential sources or when permission of the companies has been granted. Other material appearing in this volume was obtained from the trade and technical press, industry contacts, and numerous other sources.

Statistics on U.S. imports and exports, world production, and foreign country trade were compiled in the Office of Technical Data Service. The foreign trade data for the United States were obtained from reports of the Bureau of the Census, U.S. Department of Commerce. World production and trade data come from numerous sources, including reports from the Foreign Service, U.S. Department of State.

The Office of Technical Data Services also provided general guidance on the preparation and coordination of the chapters in this volume and reviewed the manuscripts to insure statistical consistency among the tables, figures, and text, between this volume and other volumes, and between this edition and those of former years.

Acknowledgment is also particularly made of the splendid cooperation of the business press, trade associations, scientific journals, international organizations, and other Federal agencies that supplied information.

The Bureau of Mines has been assisted in collecting mine production data and the supporting information appearing in the Minerals Yearbook by numerous cooperating State agencies. These organizations are listed in the acknowledgment to Volume II.

ALBERT E. SCHRECK, *Editor-in-Chief.*

Review of the Mineral Industries

By Daniel E. Sullivan [1] and Nicholas G. Theofilos [1]

Recession was evident throughout 1974 but accelerated toward the end of the year. The real gross national product (GNP) declined sharply during the first quarter and continued to decline in the next two quarters. During the final quarter the rate of decline was double that of the first quarter. There were also substantial declines in industrial employment and corresponding increases in unemployment, as strong inflation continued and consumer confidence declined. The energy crisis, compounded by the Arab oil embargo, was a major contributing factor to these problems, and the Federal Government took steps to make the United States less dependent on foreign energy sources. Monetary policy was designed to reduce the rate of growth of the money supply, and fiscal policy was characterized by a smaller deficit than anticipated, as inflation caused Federal revenues to increase faster than Federal expenditures.

Real output declined during 1974. The GNP at current prices increased 8%, but because prices rose 10% during the year, real GNP, measured in 1958 dollars, decreased 2%. Real gross private domestic investment in residential structures declined more than 27%, and real personal consumption expenditures for durable goods declined 9%. Real State and local government purchases increased almost 3%, and real personal consumption expenditures for services increased more than 1%. The Federal Reserve Board (FRB) index of industrial production declined almost 1%.

The unemployment rate increased to 5.6% in 1974 from 4.9% in 1973. The number of people employed increased during the year but because the total labor force increased at a greater rate, unemployment rose. The unemployment rate stayed near 5.1% during the first half of the year, during the third quarter it went to 5.5%, and during the fourth quarter it went to 6.6%.

The consumer price index (CPI) increased 11.0% from 1973 to 1974, the greatest rise since the post-World War II period. Although the rate of increase from quarter to quarter was consistent, there were significant shifts in the composition of the rises. During the last 3 quarters of 1974, increases in food and fuel prices no longer dominated the changes in the CPI as they had in the first quarter. After the termination of price controls in April, changes in the CPI were attributed to increases over a broader range of goods. Prices of goods and services in consumer markets as measured by the CPI, and the GNP deflator advanced at fairly steady rates during 1974, but in late spring rates of increase slowed and there were some price reductions in crude and intermediate industrial product markets. Metal prices continued to rise, reflecting large wage gains and higher fuel prices. The wholesale price index for industrial commodities increased from 125.9 points in 1973 to 153.8 in 1974.

As a result of rapid inflation in 1974, the Federal Reserve decided on a gradual reduction in the rate of growth of the money supply. This was considerably below that of 1973 and substantially below the too rapid rate of 1972. The Federal Reserve used its open market operations in order to moderate the rate of monetary expansion. The discount rate reached a record 8% in April but declined to 7¾% by yearend. Consequently, in July the commercial prime rate reached 12% at most major banks, and then fell substantially during the fourth quarter. For the whole year, the money supply rose 4.5%, down from 6.1% in 1973.

---

[1] Economist, Division of Economic Analysis.

Fiscal policy was tighter than anticipated in 1974. This was partially because inflation was greater than was expected. Federal expenditures continued to shift away from purchases of goods and services, especially defense expenditures, and toward transfer payments. An $11.7 billion deficit was projected for 1974, but the actual figure was $7.6 billion compared with $5.6 billion in 1973.

Federal activities in areas that affected minerals or the mineral economy included both continuing and special actions. The Federal Government continued to take actions to improve the economy and fight inflation. The Economic Stabilization Act Amendments of 1971, which were the basis for price controls, expired. Inflation was combated without the use of price controls. The Government took a number of steps to improve the energy situation. The subjects of mineral related bills enacted into law included energy, the environment, water, public lands, public safety, gold, and tariffs.

The 1974 research program of the Bureau of Mines was designed to promote the effective utilization of our natural mineral and fuel resources, insuring adequate mineral supplies without objectionable environmental, social, and occupational effects. Late in 1974 the Energy Research and Development Administration (ERDA) was established by Congress, and some of the research functions of the Bureau of Mines were transferred to this organization.

Energy use in the United States during 1974 fell 2.2%, the first decline in more than 2 decades. This was mostly attributed to the Arab oil embargo, higher prices for crude oil, the slowdown of the economy, and efforts by consumers to conserve energy. Consumption declined for all energy sources except utility hydropower and nuclear power. The transportation sector showed the biggest drop of all major consuming sectors. Petroleum and natural gas liquids supplied almost 46% of the energy used, compared with 47% in 1973. The production of bituminous coal, hampered by labor disputes late in the year, increased only 1.4% over that of 1973.

The year 1974 was one of shortages, uncertainties, and increased regulation of the mining industry, but at the same time the mining industry expanded and improved the technologies of mining and exploration. The exploration and development of new ore bodies continued in 1974, despite the ever-increasing risks involved. The nonferrous metals industry had the largest expenditure on pollution control equipment (as a proportion of total capital expenditures) of any industry in the United States.

Most of the world suffered serious economic strains during 1974. Rates of inflation accelerated, and the expansion of real economic activity slowed. These problems were exacerbated by the quadrupling of the price of oil. The oil price increase also caused balance of trade problems for the oil-consuming countries.

SOURCES AND USES

ALL MINERALS

Production.—Domestic raw mineral production was valued at $55.2 billion in 1974, a 50% increase from 1973. In constant 1967 dollars the figure declined more than 2% to $26.3 billion. The value of domestic production of nonmetals increased over 17% in current dollars, but in constant 1967 dollars it declined less than 0.1%. For metals the current value increased over 27% but the constant dollar value declined almost 5%. The current value of mineral fuels output increased almost 64%, however, the constant 1967 dollar value declined almost 3%. Exports of primary minerals and mineral fuels increased over 109% to $3.5 billion, and imports increased almost threefold to $19.4 billion.

The Bureau of Mines indexes of physical volume of mineral production (1967=100) generally declined during 1974 in concert with the general economic recession. The overall index declined almost 3% to 110.9 index points. The index for the average of all metals declined almost 5% to 130.4 index points, the index for the average of all nonmetallic minerals increased almost 1% to 119.7 index points, and the index for the average of all fuels declined almost 4% to 105.4 index points. Within the metals group, the ferrous metals index declined almost 7%, and the index for all nonferrous metals declined almost 4%. The index for base metals declined more than 4%, the index for monetary metals declined 8%, and the index for other nonferrous metals increased more than 6%. In the nonmetals sector the index for construction materials declined almost 2%, the index for chemicals increased more than 8%, and the index for other nonmetallic minerals increased almost 5%. In spite of the decline in the fuel index, the index of production for coal increased almost 2%. The index for crude oil and natural gas declined almost 5%.

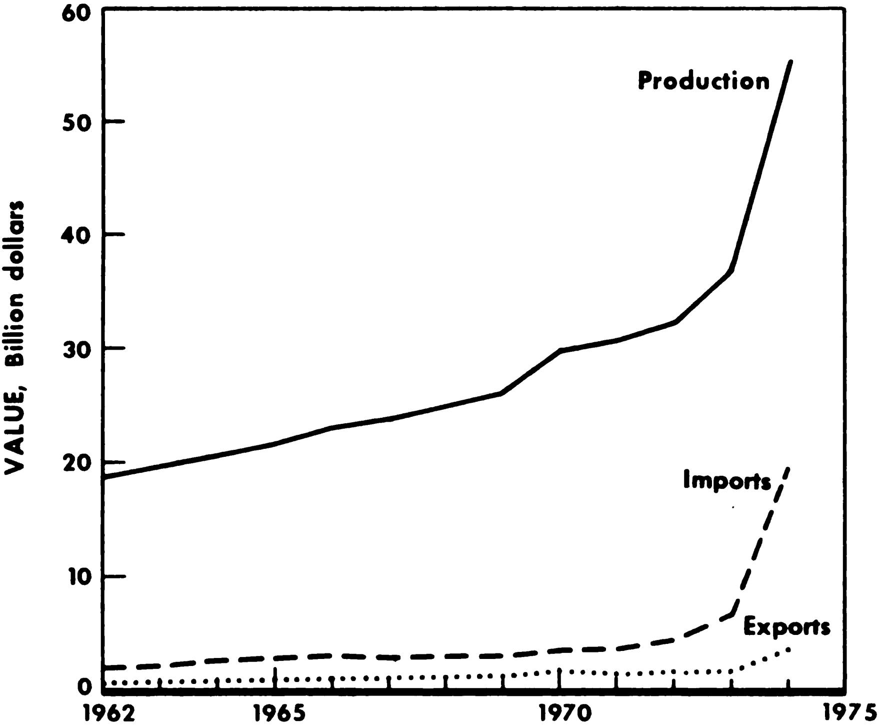

Figure 1.—Value of raw mineral production, exports, and imports.

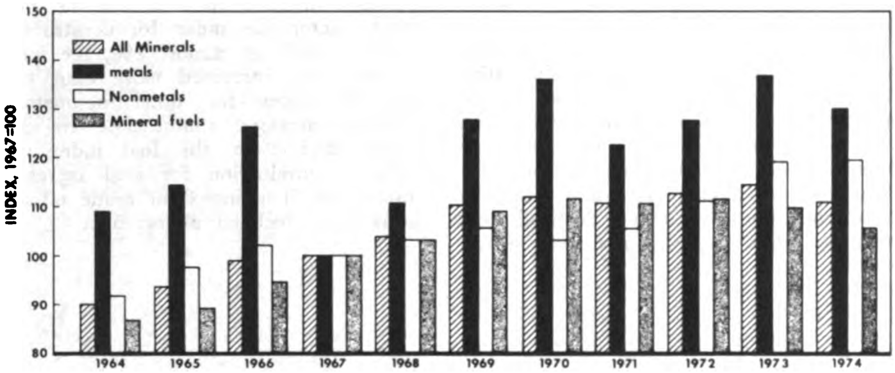

Figure 2.—Indexes of physical volume of mineral production in the United States, by group.

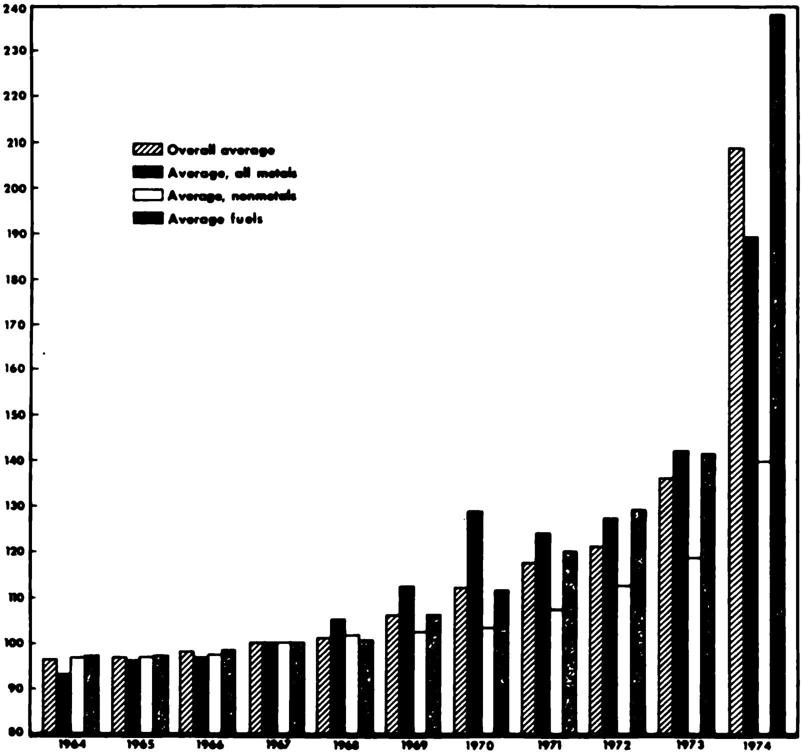

Figure 3.—Indexes of implicit unit value.

The FRB index of industrial production (1967=100) was 124.7 points for all industries in 1974. This was a decline of almost 1% from the 1973 figure. The average index for all mining showed a slight decrease to 109.4 index points. The metal, stone, and earth mineral production indexes also declined slightly. The crude oil and natural gas indexes declined about 4% each. The coal mining index increased slightly but was the only mining index to do so. The metal, clay, glass, and stone manufactured product indexes all declined during 1974. The primary metal index declined 2.3%, the iron and steel index declined 1.5%, the nonferrous metals and products index declined 2.9%, and the clay, glass, and stone products index declined 3.3%.

The FRB average index for all mining by month was 109.9 index points in January. It increased to 112.2 index points in March, then gradually declined to 110.2 index points in July, and dropped to 107.3 in August. It returned to 110.5 by October, but fell to near 105 for the remainder of the year. The monthly index for coal, oil, and gas generally followed this same trend. The coal monthly index, which was 108.7 in January, went up to 114.7 in March, but dropped to 110.3 the next month; it then increased to 118.3 in June, and dropped to 99.4 in August. For the next 2 months it was near 111; then it dropped to 67.6 in November, due to the coal strike. It returned to just about 80 for December. The oil and gas extraction monthly indexes generally followed the trend of the total mining index, except for the crude oil index, which tended to decline throughout the year. The metal, stone, and earth minerals and the metal mining indexes declined in the first half of the year, were lowest in August, returned to a high point in October, then went down a little for the remainder of the year. The stone and earth minerals index remained near 111 for the first 5 months, declined to 106.4 for June, increased to near 110 for August, was 105.0 in September, went up to near 110 for November, and declined to 106.4 for December.

The net supply of principal nonfuel minerals changed in a mixed pattern during 1974. The net supply of most ferrous metals declined during the year. Iron ore, pig iron, and steel ingot declined less than 1%, almost 6%, and almost 4%, respectively. Cobalt declined almost 9%, manganese declined over 59%, and molybdenum declined more than 36%. Tungsten declined less than 1%. Nickel and chromite both increased, by 10% and over 15%, respectively. The net supply of nonferrous metals also changed in a mixed pattern with more commodities showing increases than decreases. Aluminum, copper, and mercury all showed increases of from 6% to 9%. Lead showed an increase of more than 1%. Rutile increased almost 13%, and platinum-group metals increased more than 18%. Antimony and zinc both showed no change. Ilmenite and slag declined more than 5%; cadmium, almost 15%; tin, more than 19%; and uranium, more than 26%. There were more positive changes in the net supplies of nonmetals than negative ones. The net supplies of talc and allied minerals, crude barite, and bromine all increased between 1% and 4%. Those of finished fluorspar, sulfur, and common salt all increased from 5% to just over 6%. Potash increased over 9%, and phosphate rock increased almost 12%. The net supply of sand and gravel and that of crushed stone both declined between 1% and 2%. The net supplies of asbestos, clays, and gypsum all decreased from 6% to 8%. The net supply of mica decreased almost 15%.

Stocks and Government Stockpile.—Stocks of crude nonfuel minerals at primary producers at yearend as shown by Bureau of Mines indexes (1967=100) declined during 1974 for all selected commodities. The total index for crude minerals declined almost 13%, the crude metals index declined almost 18%, and the crude nonmetals index declined just over 3%. In the metal category, the index for iron ore declined 13%, the index for other ferrous ores declined over 37%, and the index for nonferrous ores declined less than 2%. Stocks of mineral manufacturers, consumers, and dealers at yearend as shown by Bureau indexes increased or remained unchanged during 1974 for all selected commodities. The total index for manufacturers' stocks increased almost 18%, the manufactured metal index likewise increased 18%, and the manufactured nonmetals index increased almost 10%. In the metals category the index for iron stocks remained unchanged, the other ferrous index increased 3%, the base nonferrous index increased 27%, and the other nonferrous index increased over 40%.

Producer stocks of bituminous coal and lignite declined over 7% in 1974. Those of coke declined 21%. Near the end of 1974 there was a coal miners strike which made necessary the drawing down of coal and coke stocks which is reflected in these figures. The stock figure for natural gasoline, plant condensates, and isopentane also declined. Yearend producer stocks of all other mineral energy resources and related products were higher than in 1973. The largest increase was a 42% change in petroleum asphalt; the smallest increase was 1% in the other products category. Stocks of carbon black increased almost 28%. Stocks of crude petroleum and petroleum products increased almost 7%. Within this group, stocks of crude petroleum increased over 9%, those of gasoline increased over 4%, and stocks of distillate fuel oil increased almost 2%. Stocks of natural gas increased less than 2%.

The seasonally adjusted book value of product inventories increased substantially for all the selected mineral processing industries during 1974. Petroleum and coal products increased the most, almost 50%, to $3,925 million, as of December 1974. Stone, clay, and glass products increased over 32% to $3,721 million. Inventories of total primary metals increased almost 27% to $11,861 million. Within this group, product inventories of blast furnaces and steel mills increased 23% to $5,747 million, and those of other primary metals increased over 30% to $6,114 million. The total seasonally adjusted book value of inventories for selected mineral processing industries increased almost 32% to $19,507 million during 1973.

U.S. Government inventories of basic stockpile materials were a significant part of the Nation's minerals program during 1974. Commodities of significant market value in the inventories included chromium, lead, manganese, platinum-group metals, silver, tin, tungsten, and zinc.

Exports.—The total value of selected minerals and mineral products exported during 1974 increased more than two-thirds. Exports in all sectors increased substantially: Crude nonmetallic minerals increased 71%; crude and scrap metals increased 36%; chemicals increased 26%; manufactured nonmetallic minerals increased 51%; and manufactured metals increased 72%. These increases are in current value and thus reflect increases both in quantities shipped and in prices. Since prices increased substantially during the year, especially in the fuels area, much of the general increase was the result of price increases.

In general, the geographical distribution of exports of selected mineral commodities for 1974 was similar to that of 1973, although there were major changes in specific commodities. Examples of some of the changes follow: There was a shift in sulfur and unroasted pyrites with more going to Europe and South America in 1974 instead of to North America and Asia; uranium and thorium ores and concentrates were not exported in 1974; coke, coal and briquets, including peat, mostly went to noncentrally controlled Asia in 1974, whereas in 1973 these commodities went mostly to North America; crude and partly refined petroleum all went to North America in 1974, whereas in 1973 it all went to Europe and Asia; silver, platinum, and platinum-group metals exports shifted from Asia to North America; and the share of exports of uranium and thorium and their alloys to North America increased.

Imports.—The total value of selected minerals and mineral products imported during 1974 increased by a factor of more than two and three-eighths. Imports in all sectors increased: Crude nonmetallic minerals increased 24%, crude and scrap metals increased nearly 55%, mineral energy resources increased 213%, chemicals increased 28%, manufactured nonmetallic minerals increased 6%, and manufactured metals increased 72%. Like exports, these are value figures, and as such reflect both quantity and price changes. A significant part of these increases can be attributed to changes in prices.

As was the case for exports, the geographical distribution of imports of selected mineral commodities for 1974 generally followed the previous pattern. Examples of some exceptions include lead ore and concentrate, more of which came from North America instead of South America and Oceania; tungsten ore and concentrate, less of which came from North America; and copper waste and scrap, less from North America and more from Europe and Asia. Also, nickel waste and scrap from North America increased its share; aluminum waste and scrap imports from North America decreased its share; imports of tin waste and scrap from North America increased its share; and the share of platinum-group metals, ores, concentrates, and wastes imports from North America and Asia increased and that from Africa decreased. Shares of coal, coke, and briquets imports from North America decreased and those from Europe increased; and the shares of mineral tar and crude chemicals from coal, petroleum, and natural gas from North America increased while that from Europe declined.

Consumption.—The recession of 1974 was reflected in the consumption of major mineral products. During 1973 this consumption increased substantially for most of the major mineral products, but during 1974 consumption declined for 24 of these 40 selected mineral products. Consumption of half of the selected ferrous metals declined. Iron ore consumption declined 6%; raw steel, more than 3%; metallurgical-grade chromite, 2%; and manganese ore, more than 12%. Refractory-grade chrome consumption increased almost 13%; chemical grade increased almost 22%; molybdenum, over 11%; and tungsten, almost 6%. Consumption of 6 of the 10 selected nonferrous metals declined. Consumption of primary antimony, and all zinc classes each declined more than 10%; the industrial consumption of silver and refined copper declined almost 10%; the apparent consumption of aluminum declined over 3%; and estimated private purchases of uranium declined almost 2%. Primary and secondary lead consumption increased almost 4%, primary mercury consumption increased almost 10%, platinum-group metals increased more than 8%, and ilmenite and titanium slag increased less than 1%. Consumption of 6 of the 10 selected nonmetallic minerals also declined. Consumption of asbestos declined more than 4%; cement, almost 8%; clays, almost 6%; sand and gravel, less than 1%; crushed stone, less than 2%; and sulfur, just over 2%. The nonmetallics that increased were lime, over 2%; phosphate rock, 7%; potash, over 9%; and salt, over 6%. Consumption of all the selected fossil fuels declined, as did utility electricity from conventional fuel-burning plants and the industrial generation of electricity (utility electricity from hydropower and nuclear power increased enough to cause the net generation of electricity to increase). Total energy resource inputs in terms of British thermal units (Btu) declined more than 2% to 73,141 trillion Btu. Consumption of bituminous coal declined almost 1% (coal carbonized for coke declined more than 4%); anthracite declined one-sixth. Consumption of petroleum and natural gas liquids declined almost 4%, and dry natural gas consumption declined more than 3%. Net electricity generation was slightly more than last year, as was electricity from utilities. Utility electricity from hydropower and nuclear power increased more than 9% and 35%, respectively. Utility electricity from conventional fuel-burning plants decreased more than 3%, as did industrial generation of electricity.

ENERGY

As a result of the Arab oil embargo, there was an overall national effort to curtail the use of fuels. As part of this effort the Federal Government encouraged electric utilities to switch to coal where economically feasible in an attempt to conserve oil. Reflecting this effort, energy use in the United States fell 2.2% after steady annual increases for more than 2 decades. There was also a 2.8% decrease in per capita energy use. Consumption declined for all energy sources except hydropower and nuclear power. The ratio of energy use to GNP declined slightly from that of 1973. This trend, which started in 1971, indicated that the U.S. economy was using energy in a more efficient way to create GNP, but it was not necessarily related to efficiency of energy in a physical, thermodynamic sense.

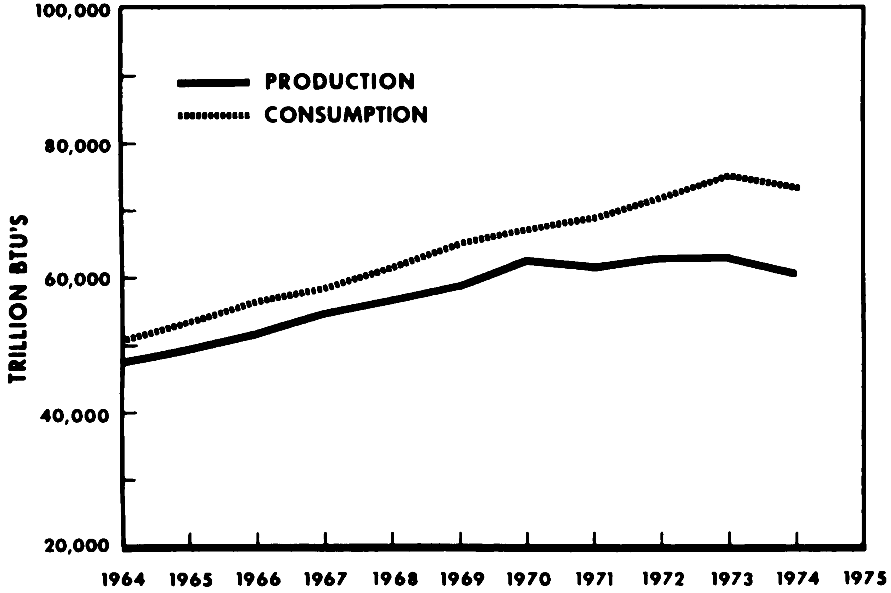

Figure 4.—Production and calculated gross consumption of mineral energy resources and electricity from hydropower and nuclear power.

Production.—Total production of mineral energy resources and electricity from hydropower and nuclear power declined almost 2% during 1974 to 61,197 trillion Btu. Anthracite, wet natural gas, and crude petroleum production all declined in terms of Btu's—over 3%, over 4%, and almost 5%, respectively. Production of bituminous coal, and electricity from hydropower and nuclear power all increased—less than 2%, over 10%, and more than 35%, respectively.

Consumption.—U.S. gross consumption of energy during 1974 decreased a little over 2%, to 73,141 trillion Btu. Consumption of all energy resources declined except for electricity from hydropower and nuclear power which increased 9% and 35%, respectively. Petroleum, excluding natural gas, accounted for about 42% of the energy consumed. Natural gas (dry) contributed slightly over 30%, and bituminous coal and lignite contributed almost 18%. The remaining energy sources individually contributed less than 5% toward the consumption of energy.

In 1974, the household and commercial sector received 43% of its total net energy input from natural gas, the petroleum input declined to 34%, 21% came from electric utilities, and the remainder came from coal. The distribution of the total net energy inputs for industrial users was natural gas 44%, petroleum 25%, coal 18%, electric utilities 11%, and all others less than 2%. Petroleum again accounted for 96% of the total net energy inputs consumed by the transportation sector. Energy inputs to electric utilities were from bituminous coal and lignite, 43%; natural gas, 18%; petroleum, 17%; hydropower, 16%; and nuclear power, 6%.

Coal.—The domestic supply of anthracite during 1974 declined 4% to 5.4 million tons. Production of anthracite declined and exports increased. Almost half of the demand was by the household and commercial sector, and the remainder was divided between industrial uses and the generation of electric power by utilities. The domestic supply of bituminous coal and lignite declined almost 1% to 551 million tons. This decline in supply occurred despite an increase in production because exports increased and withdrawals from stocks during 1974 were half of what they were in 1973. Imports of bituminous coal were more than 16 times greater in 1974 than in 1973. Electric utilities continued to be the predominant user of bituminous coal.

Natural Gas.—The domestic supply of natural gas decreased over 3% during 1974 to 21,512 billion cubic feet. Production, imports, exports, and stock additions all were less in 1974 than in 1973. Production declined almost 5%, exports declined less than 1%, imports decreased over 7%, and net stock additions were more than 81% less than in 1973. The demand for natural gas declined in all sectors except for use as a raw material for chemicals other than carbon black. The total demand declined by more than 3%.

Petroleum.—The domestic crude oil supply decreased over 2% to 4,428.7 million barrels during 1974. Production declined almost 5%, exports increased over 57%, and stock withdrawals of 1973 were more than replaced by additions in 1974. The domestic supply of refined petroleum products declined almost 4%. The demand for petroleum was down for each consuming sector. Transportation accounted for more than half of the domestic product demand.

Nuclear Energy.—Nuclear energy consumption during 1974 was 1,202 trillion Btu; this was over 35% greater than the figure for 1973. It increased to 1.6% of total energy consumption for the year; in 1973 it was 1.2% of the total.

Hydropower.—Electricity from hydroelectric plants during 1974 was 3,290 trillion Btu, over 9% greater than in 1973. This was 4.5% of total energy consumption in 1974 compared with 4.0% for 1973.

Other Energy.—Energy sources being used or considered for future use during 1974 included geothermal, oil shale, solar, wind, tidal, and biological (from organic wastes). Geothermal energy was a limited source of energy during 1974; future development depends on the discovery of new fields and their prescribed technology. Work continued on the development of oil shale as a significant source of energy. Solar wind, tidal, and biological energies were only minor or theoretical sources of energy during 1974; their development continued and their potential in the long run is significant.

EMPLOYMENT AND PRODUCTIVITY

Employment.—Employment in almost all of the selected mineral industries increased in 1974. Total mining employment increased over 6%, and within this group employment in metal mining increased 2%, employment in nonmetal mining and quarrying increased almost 3% and employment in the fuel extractive industries increased 8%. In the metal mining group, iron ore mining increased almost 14% and copper ore mining increased a little more than 1%. Within the fuels group, employment in oil and gas field services increased over 13%, employment in crude petroleum and natural gas fields increased almost 8%, employment in bituminous coal increased over 4%, and the only mining employment to decline was in other coal, which was almost 3% less than in 1973.

Total mineral manufacturing employment increased 11% to 963,800 during 1974, mineral manufacturing employment increased almost 13%, and total fuel manufacturing employment increased over 4%. Within the nonfuel minerals group, employment at blast furnaces, steelworks, and rolling mills increased over 16%, nonferrous smelting and refining employment increased over 5%, and the only mineral manufacturing industries to show declines in employment were fertilizers, complete and mixing only, and hydraulic cement, which each decreased over 3%.

Within the fuel manufacturing sector, employment in petroleum refining increased 5%, and employment in other petroleum and coal products increased almost 2%.

Hours and Earnings.—Average hourly earnings in the extractive industries increased nearly 10% for both nonfuels and fuels. The hours worked declined more than 1% in the nonfuels industry and increased almost 3% in the fuels industry, causing average weekly earnings to increase less than 9% for the former while increasing more than 11% for the latter. Within the nonfuels industry average hourly earnings increased 14.1% for metal mining and 8.1% for nonmetallic mining and quarrying, although in both industries the hours worked declined, causing average weekly earnings to increase at a slightly slower rate than that for the hourly figures. Within the metal mining sector, average hourly earnings for iron ores increased over 19%, average weekly hours increased almost 2%, and average weekly earnings increased almost 22%. Average hourly earnings in copper mining increased almost 13%, but average weekly hours declined almost 3%, so average weekly earnings increased less than 10%. In the extractive fuels industries, average hourly earnings in coal mining increased about 9%, and average weekly hours declined about 4%, causing average weekly earnings to increase just over 4%. Average hourly earnings in the crude petroleum and natural gas industries increased almost 14%, average weekly hours increased almost 3%, and average weekly earnings increased almost 17%.

Average hourly and weekly earnings for the manufacturing sector both increased about 11% as weekly hours remained unchanged. Within this group all of the selected industries showed little change in weekly hours. Fertilizers showed increases in hourly and weekly earnings of more than 10%; hydraulic cement, greater than 6%; blast furnaces, steel and rolling mills, more than 14%; nonferrous smelting and refining, nearly 12%; petroleum refining and related industries, nearly 8%; petroleum refining also near 8%; other petroleum and coal products, more than 6%.

Wages and Salaries.—During 1973 (latest data available) total wages and salaries for all industries continued to increase. In the mining sector the increase was almost 10%, and in the manufacturing sector the increase was almost 12%. The average earnings of full-time employees also increased in 1973, but at a slower rate than in 1972. The mining sector employees received an annual average of $11,448, about 7% over 1972. Average earnings in manufacturing increased a little over 6% to $9,758 per year. The average earnings per full-time employee for all industries was $9,106, an almost 6% gain from the 1972 figure.

Labor Turnover Rates.—The accession rate (hires and rehires) during 1974 declined for the manufacturing sector and for most of the nonfuel mineral industries. It increased for nonferrous smelting and refining and for selected fuel industries. In the manufacturing sector the decline was over 12%. The greatest decline was 20% for blast furnaces, steel and rolling mills. The accession rate for nonferrous smelting and refining increased almost 4%, and that for coal mining increased almost 12%. The separation rate increased for manufacturing and for most selected mineral industries; it declined for metal mining and coal mining. In the manufacturing sector the increase was over 4%. The separation rate in the hydraulic cement industry increased almost 38%, for blast furnaces, steel and rolling mills it was almost 10% higher than in 1973, and for nonferrous smelting and refining it was up 4%. The metal mining separation rate declined almost 9%, as did the rate for copper ores; the rate for iron ores was unchanged. The rate for petroleum refining and related industries increased 9%, although for petroleum refining it was unchanged. For coal mining, the separation rate declined almost 19%, the greatest decline among the selected industries. The layoff rate increased two-thirds in manufacturing, more than doubled in hydraulic cement, and increased three-fourths in the blast furnace, steel and rolling mills industry; it remained unchanged in the nonferrous smelting and refining industry. In metal mining the layoff rate remained unchanged, although it declined 20% in the iron ore industry and tripled in the copper ore industry. In petroleum refining and related industries the layoff rate increased two-fifths, although for petroleum refining itself it declined one-fifth. In the coal mining industry it declined by one-third.

Productivity.—Indexes of labor productivity for selected mineral industries for 1973 (latest data available) were mixed. The indexes of output of crude copper ore and of recoverable copper metal mined per employee, production worker, and production worker man-hour all declined at rates between 4% and just over 7%. The same indexes for crude and usable iron ore all increased between just under 5% and just over 11%. The indexes for refined petroleum increased between 7% and 9%; for bituminous coal the index per employee declined over 1%, the index per production worker declined over 2%, and the index per production worker man-hour increased almost 1%.

PRICES AND COSTS

Index of Average Unit Mine Value.—The index of average unit mine value is similar to the index of implicit unit value in that both are designed to show relative price changes of mineral commodities, but it is different in that it is constructed directly from quantity and value data while the index of implicit unit value is the result of dividing two other indexes, a value index and a volume index, which are constructed directly from the data. For further information on the subject, see Bureau of Mines Information Circular 8275.[2]

The index of average unit mine value shows the inflation manifested in mineral prices. The overall average index increased by almost 56% to 212.4 index points. The metals index increased almost 34%, the nonmetals index increased almost 18%, and the fuels index increased almost 69%. In the metals category, the ferrous metals index increased over 27% and the nonferrous metals index increased almost 40%. Base metals prices as reflected in the index, increased 36%; monetary metals, 71%; and other nonferrous metals, almost 28%. In the nonmetals category, the construction index increased 13%, the chemicals index increased 41%, and the other nonmetallic minerals index increased almost 13%. In the fuels category, the index for coal increased almost 77%, and the index for crude oil and natural gas increased almost 66%.

Index of Implicit Unit Value.—The index of implicit unit value (1967=100), as mentioned above, is similar to the index of average unit mine value in that both are intended to show changes in the relative prices of mineral commodities. For this reason it is not surprising that the results of the two indexes are not dissimilar. The overall average for the index of implicit unit value increased over 53% to 209.1 index points. The metals index increased over 33%, the nonmetals index increased over 17%, and the fuels index increased over 68%. In the metals category, the ferrous metals index increased over 27% and the nonferrous metals index increased over 36%. The base metals index increased 34%; monetary metals, 74%; and other nonferrous metals, almost 30%. In the nonmetals category, construction increased almost 13%, chemicals, almost 41%, and other nonmetallic minerals, almost 14%. In the fuels category, coal increased almost 77% and crude oil and natural gas almost 65%.

Prices.—The wholesale price indexes for selected metals, minerals, and fuels (1967=100) all increased significantly in 1974. The index for all commodities increased almost 19% to 160.1 index points; that for all commodities other than farm and food increased over 22% to 153.8 index points. The index for metals and metal products increased more than 29% to 171.9. Many of the indexes for selected metals and metal products increased at about the same magnitude. Exceptions included iron ores, which increased the least, less than 16%; the ones that increased the most were: Iron and steel scrap, almost 88%; slab zinc, which increased almost 70%; aluminum ingot, which increased more than 49%; pig iron and ferroalloys, increasing more than 45%; and primary metal refinery shapes, increasing more than 42%. The index for nonmetallic mineral products increased almost 18% to 153.2 index points. Within the nonmetallic group the indexes all increased between just above 8% for sand, gravel, and crushed stone to almost 131% for phosphate rock. The index for structural clay products increased less than 10%, other nonmetallic minerals increased 47%, phosphates increased more than 58%, fertilizer materials increased more than 61%, nitrogenates increased more than 68%, and bituminous binders increased almost 76%. The price index for fuels and related products and power increased more than 55%. The price indexes for most selected fuels increased at about this magnitude. Exceptions included electric power, which increased a little more than 26%; gas fuels, which increased 28%; crude petroleum, which increased more than 68%; and refined petroleum products, which increased almost 74%.

---

[2] Johnson, E. E. Index Numbers for the Mineral Industries. BuMines IC 8275, 1965, 85 pp.

Prices of mineral energy commodities increased substantially during 1974. The average price of bituminous coal at merchant coke ovens increased almost 85% to $36.50 per net ton; the average sales realization prices for anthracite increased between 60% and 71% to between $27.61 and $31.06 per net ton. The average price of crude petroleum at the well increased more than 73% to $6.74 per barrel; the average dealers' price of gasoline excluding taxes increased almost 57% to 30.53 cents per gallon. The average prices of residual fuel oil more than doubled. No. 6 fuel, maximum 1% sulfur, at Philadelphia, was $11.95 per barrel; No. 6 fuel, maximum 0.3% sulfur, at Philadelphia, was $13.11 per barrel; and the average price of bunker C fuel, at all gulf ports, was $9.59 per barrel. The average price of No. 2 distillate fuel oil at Philadelphia almost doubled to 25.26 cents per gallon, and at all gulf ports it increased more than 44% to 29.80 cents per gallon. The average value at the well for natural gas increased almost 41% to 30.4 cents per thousand cubic feet, and at the point of consumption it increased almost 34% to 88.8 cents per thousand cubic feet.

During 1973 (latest data available) the average cost of electrical energy continued to increase at about the same rate as in recent years. Alaska and Hawaii had the highest electricity costs, followed by the New England and Middle Atlantic areas. The lowest cost of electrcial energy was found in the East South-Central region because of the Tennessee Valley Authority. The average cost of electricity in the residential market increased 0.1 cent to 2.4 cents per kilowatt-hour. Most geographic areas increased except the West North-Central, the West South-Central, and the Mountain area which remained the same as in 1972. In the commercial and industrial sectors the average increase in 1973 was 0.1 cent per kilowatt-hour. The only areas to show declines in the cost of electricity in the industrial and commercial sector were the East North-Central and the West North-Central.

Principal Metal Mining Expenses.—The index of principal metal mining expenses (1967=100), following the price trend for the economy as a whole, increased 26% to 171 index points. The labor component and the electrical energy component of the index increased at the same rate as the total index, to 179 and 163 index points, respectively. The supply component increased less than 23% to 157 index points, and the fuel component increased almost 43% to 208 index points.

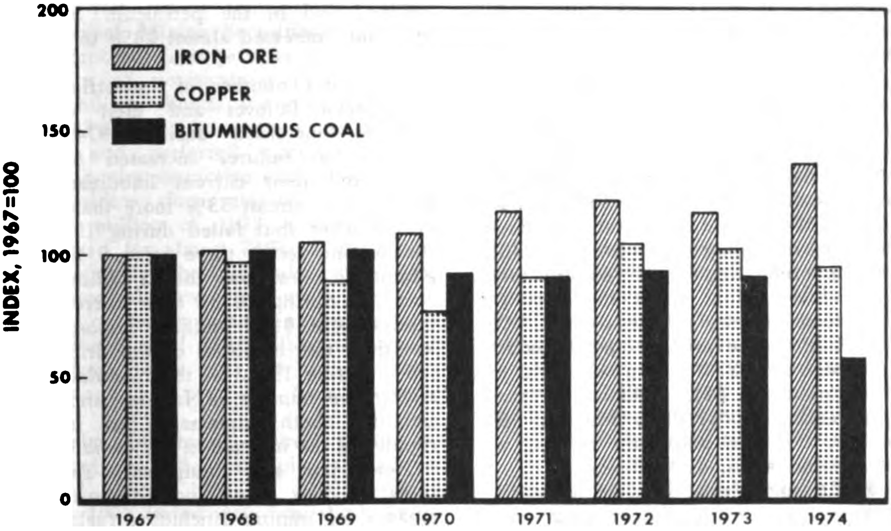

Figure 5.—Index of labor costs per dollar of product.

Costs.—The indexes of relative costs and productivity (1967=100) reflected the inflationary condition that prevailed in the 1974 economy. For iron ore, copper, and bituminous coal, the 1974 indexes of labor costs per unit of output all increased—almost one-third for iron ore, one-fifth for copper, and one-twelfth for bituminous coal. The indexes of value of product per man-period for these commodities also all increased—less than 2% for iron ore, more than one-sixth for copper, and nearly three-fourths for bituminous coal. The index of labor costs per dollar of product increased by more than one-sixth for iron ore, but declined almost 7% for copper and by almost three-eighths for bituminous coal. These figures reflect the mixed impact of inflation on productivity. The petroleum indexes of labor costs per unit of output and of value of product per man-period both increased by about one-tenth during 1973 (latest data available), and the index of labor costs per dollar of product declined almost 4%. During 1972, in the petroleum sector, the index of labor costs per unit of output increased about one-tenth, and the index of value of product per man-period declined slightly, resulting in an increase of about one-tenth in the index of labor costs per dollar of product.

Price indexes for mining construction and material handling machinery and equipment (1967=100) all increased by at least one-tenth during 1974. Five of the nine indexes showed increases of at least one-sixth, with mining machinery and equipment increasing the most. The index for portable air compressors again increased the least.

INCOME AND INVESTMENT

National Income Generated.—In 1973 (latest data available) national income originating in all industries rose almost 13% to $1,066 billion. In the mining sector, crude petroleum and natural gas accounted for the largest share, $4.0 billion. Coal mining accounted for the next largest share of income generated, $2.4 billion, an 8% increase from 1972. Mining and quarrying of nonmetallic minerals increased almost 16% to $1.8 billion. Metal mining showed the largest increase, increasing 23% to $1.2 billion. Income originating in the manufacturing sector increased at about the same rate as mining income, a little over 13%, to $2.9 billion. The primary metals industry accounted for $22.0 billion; chemical and allied products, $21.0 billion; the stone, clay, and glass products industry, $9.9 billion; and the petroleum refining and related industries, $9.4 billion.

Profits and Dividends.—The average annual profit rate on shareholders' equity in all manufacturing industries increased more than two percentage points during 1974 to 14.9%. Of the selected mineral manufacturing industries, only one did not show a substantial increase in its annual profit rate. Stone, clay, and glass products showed a profit rate of 10.6%, which was 0.6 percentage point less than the 1973 figure. The average annual profit rate for primary metals increased almost two-thirds to 16.4%, for primary iron and steel the profit rate increased more than three-fourths to 16.8%, and for primary nonferrous metals the profit rate increased almost one-half to 15.8%. The profit rate for chemicals and allied products increased almost one-fourth to 18.3%; for petroleum it increased more than four-fifths to 21.0%.

Total dividends for all manufacturing increased almost 10% to $19,456 million during 1974. Total dividends increased for all selected mineral manufacturing corporations except primary nonferrous metals, which declined 11% to $483 million. Total dividends for all primary metals increased more than 10% to $1,216 million, and for primary iron and steel they increased more than 31% to $734 million. Total dividends in the stone, clay, and glass products industries increased less than 1% to $450 million; for the chemicals and allied products industries the increase was almost 19% to $2,800 million; and in the petroleum industry dividends increased almost 18% to $4,070 million.

The total number of industrial and commercial failures and their current liabilities increased during 1974. The number of failures increased 6% to 9,915 and their current liabilities were $3.1 billion, almost 33% more than those of the firms that failed during 1973. In the mining sector there were 9 failures, almost 72% less than the 32 failures that occurred during 1973; their current liabilities were $10.1 million, almost 58% less than the liabilities of the firms that failed during 1973. In the manufacturing sector, the number of failures and their liabilities both increased, but not as rapidly as the increase in the overall rates.

New Plant and Equipment.—Expenditures for new plant and equipment increased for mining (including fuels) and for all but one of the selected mineral manufacturing industries. Expenditures by firms in the mining industry increased 16% to $3.18 billion; those by all manufacturing increased 21% to $46.01 billion. Expenditures in the primary iron and steel industry increased almost 54% to $2.12 billion; expenditures in the primary nonferrous metals industry increased almost 40% to $2.33 billion; in the stone, clay, and glass products industry, expenditures declined more than 3% to $1.44 billion; in the chemical and allied products industry, expenditures increased almost 28% to $5.69 billion; and in the petroleum industry expenditures for new plant and equipment increased almost 47% to $8.00 billion.

Plant and equipment expenditures of foreign affiliates of U.S. companies in mining and smelting changed direction in 1974, increasing to $1,252 million. Expenditures decreased only in Canada and remained constant in Europe. Latin American expenditures continued to increase, this year by 47%, reaching $286 million. The remaining areas in the world showed an increase of 65%, a sharp contrast to last year's 29% decrease. In the petroleum sector, plant and equipment expenditures continued to rise in all areas. Expenditures in Europe increased almost 41%, followed by Latin American with 35%. Manufacturing plant and equipment expenditures also rose in 1974. Europe had the largest amount in dollars, $6,316, followed by Canada, $2,122.

Issues of Mining Securities.—Estimated gross proceeds from primary security offerings for all corporations in 1974 were $37.9 billion. Bonds accounted for more than 83% of this; common stock, over 10%; and preferred stock, 6%. Proceeds in the extractive industries totaled $980 million, down almost 9% from the $1,073 million of 1973. Common stock accounted for almost 74% of this figure, and bonds for the remainder; there were no proceeds from preferred stock in 1974. For the manufacturing industries in 1974 the total of $10.4 billion was almost 95% from bonds, over 4% from common stock, and just over 1% from preferred stock.

Foreign Investment.—Direct private investment of U.S. companies abroad increased almost 14% to $107.3 billion during 1973 (latest data available). Petroleum investments were almost 28% of this total, or $29.6 billion, which is nearly a 13% increase from the previous year. In general the percent of petroleum investments received by developing countries was greater than the percent of total investments they received. Petroleum investments in developed countries totaled $16.4 billion. Europe accounted for about one-half of this, and Canada accounted for more than one-third. Petroleum investments in developing countries totaled $10.4 billion. Countries in the Western Hemisphere accounted for more than two-fifths of this, and other Africa and the Middle East each accounted for about one-fifth.

U.S. direct investments in foreign mining increased almost 5% to $7.5 billion during 1973 (latest data available). The developed countries received almost 64% of these investments, or $4.8 billion. More than three-fourths of mining investments in developed countries was in Canada. Mining investments in developing countries were $2.7 billion; almost half of this was invested in Latin American Republics.

The value of foreign direct investments in the United States in 1973 (latest data available) was $17.7 billion, an increase of almost 25%. Investments in the petroleum sector increased almost 37% to $4.4 billion, which is almost 25% of the total foreign direct investments in the United States.

TRANSPORTATION

The total quantity of major minerals and mineral energy products transported by railroad and water during 1973 (latest data available) increased by 60,751 million short tons or almost 4% over that of 1972 to 1.7 billion short tons. Almost 59% of all commodities transported by rail and over 83% of all commodities transported by water were mineral products. The latter represented a small decrease from 1972. About 63% of the selected metals and minerals, except fuels, were transported by rail, and 56% of selected mineral energy resources and related products was transported by water.

In the metals and minerals except fuels category, the volume of commodities transported by rail increased over 11% to 451.9 million short tons. Of this total, almost 60% consisted of four commodities: Iron ore and concentrates, crushed and broken stone, iron and steel ingot, etc., and sand and gravel. Rail transport for almost all of the selected minerals increased in 1973 except for sand and gravel and building cement. The largest increases occurred in gypsum, almost 217%, and nonferrous metal scrap, over 102%. (Note.—In the 1973 chapter of this volume, some of the data for rail transport in 1972 were erroneously reported. The corrected figures are given in this chapter.)

Water transportation of metals and minerals, except fuels, increased almost 6% to 259.9 million short tons. The largest increase by volume occurred in the iron ore and concentrates category, from 73.5 million short tons in 1972 to 84.0 million short tons in 1973, by limestone flux and calcareous stone, which increased from 31.6 million short tons to 36.5 million short tons. In general, water transportation of the selected metals and minerals, excluding fuels, did not show the increases shown by the corresponding rail transportation figures. Almost half of the commodities declined in 1973; the largest decline by volume was in fertilizers and fertilizer materials.

A total of 443.8 million short tons of mineral energy resources and related products was transported by rail in 1973; this was more than 2% greater than 1972. By volume the largest commodity transported was bituminous coal and lignite. This represented almost 84% of the total. The largest increase was a more than 67% increase in crude petroleum.

Water transportation of mineral energy products totaled 567.6 million short tons in 1973, nearly 2% below that of 1972. Again, coal accounted for the largest share of the tonnage transported by water. The largest increase occurred in coke, 56%, and miscellaneous petroleum and coal products, 20%. Decreases of significance occurred in crude petroleum, 13%, and kerosine, 11%.

A total of 967,700 miles of gas pipeline existed in 1973 (latest data available), an almost 2% increase from the 1972 mileage. Total petroleum pipeline mileage in 1974 increased to 222,000 miles from the 1973 level of 219,000 miles. It was distributed among crude gathering systems in field operations, 31%; large-size crude trunklines, 34%; and petroleum product pipelines that extend from refineries to extraction terminals, 35%.

RESEARCH ACTIVITIES

National expenditures for research and development activities by all industries in 1973 (latest data available) totaled $20.9 billion, an 8% increase from the 1972 figure. Of this total, 61% was spent by private industry and 39% by the Federal Government. These proportions were not significantly changed from 1972.

Research and development expenditures in the petroleum refining and extractive industries totaled $504 million in 1973, almost an 8% increase from the 1972 figure of $468 million. Private industry financed 97% of the total research in petroleum refining and extractive industries and 90% of the chemical and allied products industries research. The remainder was financed by the Federal Government. During 1972, private expenditures made up 98% of the total research expenditures in the petroleum refining and extraction industry and 90% of the total research expenditures in the chemical and allied products industry.

Bureau of Mines.—The research program of the Bureau in 1974 continued to emphasize the efficient use of our natural mineral and fuel resources in order to insure adequate mineral supplies without objectionable environmental, social and economic effects. Bureau research concentrated on the following areas: Mining (including health and safety and explosives), metallurgy, resource recovery and pollution abatement, coal, petroleum, oil shale, economics, and helium. During the latter part of 1974, the law establishing ERDA was passed by Congress, and the energy research functions of the Bureau of Mines were to be transferred to that organization.

Bureau of Mines funding obligations for mining and mineral research and development were $66.1 million during fiscal year 1974, almost a 15% decrease from 1973. Funds for applied research decreased by almost $10 million, for basic research the decrease was $1.2 million, and for development the decrease was $463,000. The overall decrease in the Bureau's funding obligations reflected the transfer of some of the research activities that were assigned to ERDA. The obligations for fiscal year 1975 were estimated to be almost double at $116.2 million. Most of this increase was estimated to go towards applied research and development; funds for basic research were estimated to decline in 1975.

Bureau of Mines funding obligations for total research were $30.5 million in 1974, a 26% decrease. Funds for the engineering sciences were $23.9 million; for the physical sciences, $5.3 million; for the mathematical sciences, $0.5 million; and for the environmental sciences, $0.8 million. The estimated figure for total research for 1975 was $53.6 million. Highlights of accomplishments of Bureau research programs, including work in progress, are described in the following pages.

Mining.—The full-scale demonstration of shortwall mining in Kentucky continued during 1974. Using a self-contained powered roof support system, a first shortwall panel in the 54-inch Elkhorn No. 3 coalbed was completed in about 3 months. The 150-foot-wide by 2,400-foot-long panel was mined by a nine-man face crew with an average production of 430 tons per shift. Measurements of ground movement, bed separation, and stress in and around the panel provided information on the effect of shortwall mining on the surrounding rock. One company in the Ohio River Valley successfully used the shortwall system to attain full pillar extraction where less than 50% recovery had been the norm. Under the cooperative agreement, the props and pillars were monitored at this operation during the extraction of four panels.

Work continued on the pumpable, fiberglass-reinforced polymer bolt. Physical properties of a pumpable 1-¾-inch bolt compared favorably with those of a fully resin-grouted steel bolt, and pull-test strength was greater than that developed by mechanical anchor in similar rock. The mechanical problems of replacement were the focus of attention in 1974, and field tests in an eastern and a western coal mine were planned. Principal advantages of the pumpable bolt will be the use of bulk handling methods for materials, amenability to remote placement or automation, adaptability to any length bolt, and particular adaptability for low-coal installation.

Preliminary results of a study of single-entry development for longwall mining indicated that the single entry is more stable, particularly when compared with double-entry intersections. Ventilation studies showed that health and safety standards can be met while driving the single entry. This system will reduce development time and increase coal recovery, thereby reducing costs.

Microseismic instrumentation and techniques used in a western coal mine have proven to offer a means of determining where bounces are most likely to occur and of estimating the overall stability of these areas. Work was continuing to refine these methods and improve their effectiveness. One unstable area was delineated some 2 weeks prior to the occurrence of a large bounce with failure.

Continuous monitoring of an open pit mine in Nevada was being conducted by a computer-controlled microseismic system which detects, records, and triangulates rock noise generated in the pit wall. During March the mine operator was notified that increased microseismic activity had been detected in the north wall and several small cracks had occurred shortly thereafter. The company verified that movement was taking place and took steps to protect or shift the main haulage road. Later in the month this zone failed but caused no delay in mining.

The first field test of electrokinetic densification of hydraulic backfill was conducted at a mine in Idaho. Direct current was applied to hydraulic fill 4 feet deep in a 4- by 90-foot underground opening for 3 hours, consuming 50 kilowatt-hours of power. Slimes, which normally remain soft indefinitely, became hard enough to support men and equipment. After an additional 12 hours (using 280 kilowatt-hours), an average surface hardness of 350 pounds per square inch was achieved. This test demonstrated that unclassified hydraulic backfill can be electrokinetically densified effectively and safely with low power consumption.

Suitable control measures applied to the chain conveyor of a coal loader reduced the noise generated by the machine in an underground coal mine from 108 decibels on the A scale (dbA) to 95 dbA. Fieldworthy muffler and jacket assemblies for pneumatic drills that maintain noise levels at 90 dbA were developed and evaluated. A survey of noise sources in coal preparation plants was completed and suitable control procedures were recommended. The dynamic range of Bureau-developed audio dosimeters was extended to provide coverage down to the 85dbA being considered for new noise standards. A stereo version of the discriminating earmuff was developed that gives the miner the directional information necessary to assess roof noises while providing excellent protection above 90 dbA.

Two prototype passive water barriers developed on the basis of trials in the Bureau's Experimental Mine were found to be effective against dust explosions. The barriers are activated by static pressure forces instead of the usual dynamic wind forces. Novel machine-mounted and portable methane sampling systems were being evaluated underground. The portable system allows a 20-minute gas check at the face without exposing the operator to unsupported roof. Other new instrumentation included a prototype oxygen deficiency alarm that incorporates a rate of change detection for oxygen levels and approved prototype low-velocity anemometers and low-velocity alarms ready for field testing.

The Bureau of Mines, through two research contracts, has developed and field-tested two prototype automatic fire sensing and suppression systems for large mobile vehicles. The systems sense either heat or light from a fire, warn the driver of the hazard, and then automatically extinguish with pressurized B–C class powder. They can also be activated manually by the driver from the cab or at ground level.

As an extension of methane drainage research and in light of current concerns over energy conservation, in January 1974 a multipurpose borehole in West Virginia was connected to a gas transmission line. This borehole has been producing pipeline-quality gas at 600,000 to 700,000 cubic feet per day for almost 2 years. Four horizontal boreholes in the coalbed at the same mine have produced more than 300 million cubic feet of pipeline-quality gas in 330 days.

An experimental procedure was used successfully to drill a degasification hole from the surface, penetrating the coalbed 700 feet below at a glancing angle and continuing into the coalbed for more than 400 feet. This drillhole has produced 25,000 cubic feet of gas per day.

Hydraulic fracturing techniques were used on a borehole in Alabama and produced vertical fractures without harming the overlying rock strata. Gas production from the hole increased from 4,000 cubic feet per day to 50,000 cubic feet per day.

Field studies using a model of a high coal entry containing a continuous miner and a shuttle car showed that with exhaust ventilation, dust concentrations around the operator could be reduced by 99% when the brattice-to-face distance was decreased from 30 feet to 10 feet. Brattice was more effective than tubing in reducing dust when located within 20 feet of the face.

In a study of dust suppression by water sprays, water was found to reduce dust much more effectively when sprayed on the loading pan of the continuous miner than when sprayed on the cutting head.

Satisfactory personal protection has been achieved by incorporating into an ordinary miner's helmet, a blower device that forms a protective curtain of air across the wearer's face. Based on the same principle, the canopies of three mining machines have been equipped with blower devices that surround the operator with a curtain of clean air.

A prototype battery-powered, manually operated rescue and surveillance vehicle for use in postdisaster rescue efforts in underground mines was developed and tested. The vehicle transports a two-man rescue team and has rescue, life support, gas-sensing, and communications equipment and a trailer for transporting two injured miners or supplies.

Development was completed on a new prototype hoist radio system for 10,000-foot-deep shafts that can be quickly deployed in an emergency. The system uses novel circuitry techniques to eliminate the dead spots usually encountered in deep hoist-shaft communication operations.

The trapped miner electromagnetic location system, originally developed for use in coal mines, was modified and performed successfully in hard rock mines to depths up to 4,000 feet. The system may not be usable in all types of mines since the conductivity of the overburden affects the range.

In research on the formation of toxic atmospheres underground, a study of the oxidative thermal degradation of mine conveyor belting and its components indicated that polyvinyl chloride compositions produced the most toxic products and styrene butadiene rubbers, the least. A handbook on sampling methodology for airborne toxic dusts other than coal and silica dusts was prepared as a guide for mine inspectors.

A prototype miniaturized battery-operated device for the simultaneous analysis of carbon dioxide, nitrogen dioxide, and methane successfully detected concentrations of CO and NO_2 at low parts per million levels. A novel method of controlled molecular gas diffusion was used to develop a simple, fairly accurate prototype device for determining exposure to NO_2 on an individual basis in a daily or weekly timeframe. Based on use of selective electrochemical cells, two prototype portable battery-operated instruments were developed that simultaneously monitor CO, NO_2, and O_2 in the underground environment and warn of unsafe levels. A dosimeter was developed that employs a selective permeable membrane to determine time-weighted averages of NO_2 over 6- to 8-hour periods. Performance of the dosimeter was not affected by spatial orientation, a fact which should facilitate personal sampling.

A small solid state radon-daughter dosimeter, operating off a cap lamp battery, gave very satisfactory results in extensive laboratory and field tests. Other monitoring devices in the prototype stage included a moving-belt dosimeter and several diffusion-chamber dosimeters. Development of a high-working-level personal alarm reached the prototype stage.

Over 50 coating materials were tested to determine their ability to stop radon gas emissions. Laboratory tests demonstrated that up to 100% of the radon emanation in uranium ore specimens can be stopped by these coatings. Underground testing of six coatings demonstrated that over 60% of the radon emanation can be stopped. A water-based epoxy and a Saran latex were the easiest materials to spray. The water-based epoxy is also considered safe for use in coal mines to prevent shale degradation.

Guidelines were drawn up for complete mine communication systems, and installation of such systems was begun in a coal mine and a metal mine. The feasibility of monitoring a major air split was demonstrated using a system installed in two sections of an underground coal mine. A miniaturized system for monitoring methane, carbon monoxide, air velocity, temperature, and rate of temperature change was developed and operated with satisfactory results.

Progress in providing candidate illumination systems to implement proposed lighting standards proceeded with successful in-mine evaluations of various portable and machine-mounted luminaires and the development of second-generation-type hardware. Lucalox and fluorescent fixtures were installed on a continuous miner and a loader. A combination of mercury vapor and fluorescent lights was installed on a cutting machine. Fluorescent lighting was provided for a conventional section in a Kentucky mine and on the boom of a continuous miner to supplement existing mercury vapor lights. Fluorescent lighting was installed experimentally at several longwalls to evaluate this type of illumination for this particular application. New hardware that performed successfully in preliminary tests in the field included portable task lamps for both high and low coal to provide supplementary illumination for machine repair and timbering, and a new fluorescent cap lamp that provides improved peripheral vision.

A study was completed on the state of the art of protective canopies, and the minimum size of entry in which a piece of electric face equipment with canopy can be safely operated was defined. In research to equip low-coal machinery with canopies, acceptable versions have been developed for face drills, cutters, and loaders. Design criteria developed for panic bars are providing design guidance to coal mine operators and mine equipment manufacturers. A shuttle car was equipped with automatic steering using guidance sensors developed earlier. Except for a manual input signal to initiate turns, the resulting steering system is completely automated.

A contract study of surface coal-mining operations and surface work areas of underground coal mines produced a detailed analysis of hazardous problems and proposed solutions to reduce or eliminate them. The solutions emphasized equipment design changes, the addition of safety devices or warning systems, and changes in operating practices and procedures.

Long-term demonstrations of equipment and procedures developed through the inherently safe mining systems research program for both conventional and continuous mining were started in 1974. Specific safety innovations on the equipment for the conventional section included rotatable, suspended cabs on the shuttle cars, with automotive-type controls which reverse automatically with the rotation of the cabs. Face drills and cutting machines are equipped with "joysticks" to combine control functions and adjustable cabs. An automated roof-bolting machine, which can be remotely operated from an adjustable protective cab, is used as the section bolter. A drum-type continuous miner has been modified with the addition of four on-board semiautomated roof bolters with magazine storage for up to eight bolts. Protective cabs mounted on the lengthened tailboom provide stations from which the miner and roof bolter operators control their respective functions. An extensible belt system employing one tram (surge) car and several drive storage units completes the continuous face equipment.

A completed study of the feasibility of hydraulic transportation in underground coal mines showed that although a hydraulic haulage system has higher initial costs, it is safer and lower in overall cost than conventional haulage systems. A basic design for a large hydraulic transportation test facility, incorporating 6-, 12-, and 18-inch pipelines with vertical and horizontal sections and including solids size control and multiple-feed capabilities, was completed. In experiments simulating face haulage in different height seams for shortwall and room and pillar mining, continuous-face haulage outproduced shuttle car haulage even when the continuous-mining rate was drastically reduced. Reports of Invention were submitted for a flexible face belt conveyor capable of following either loading or continuous-mining machines and for a feeder operating on a peristaltic action principle for injecting coal into pipelines.

A new conventional mining system was being developed which consists of four closely integrated pieces of equipment. The coal is cut by a unique full-face, twin-auger machine which offers a unique sump-cycle capable of 16 feet of penetration while the operator is always under supported roof. Coal is transported away from the face by a specialized load-haul-dump unit which offers speed, ease of operation, and a design that stresses safety. Coal is discharged at the belt line by a special belt feeder that can easily handle the large car load and can disperse the load at any desired rate. The roof is supported either by a new roof truss system utilizing wire rope or by conventional roof bolts installed by a Roofroper. The four machines together form a complete, safe, and economical system.

In research on incendivity of explosives, the effects of stemming, explosive wrapper, and excessive NO_x production on the probability of ignition of natural gas (W_{50} value) and natural gas-coal dust (W_{cdg} value) atmospheres were investigated. A computer-developed relationship between W_{50} and W_{cdg} and explosives composition was refined to produce results with a correlation coefficient of 0.95 for approximately 50 different explosive formulations.

An underwater test was developed for determining the hazards of marginally explosive material. The test was being considered as a standard by the ASTM. An extensive study yielded preliminary results indicating that blasting agents that are insensitive to a No. 8 blasting cap cannot be initiated by conventional rifle ammunition when unconfined. In research on explosives identification, a method for coating rare-earth phosphors was developed which successfully eliminated their tendency to sensitize certain explosives.

The first two stages of a three-stage prototype borer were fabricated and field-tested. The borer drilled a 24-inch hole in a medium-strength limestone at rates in excess of 21 feet per hour while requiring only 2,500 pounds of thrust. The borer achieved good cuttings removal and sustained no apparent wear or damage. The successful test cleared the way for the fabrication of the third powered stage and the assembly of a complete 42-inch-diameter three-stage prototype borer.

Full-scale field experiments were conducted to determine the effect of relief hole diameter in burn cuts on the length of pull and damage to country rock. Blasting results indicated the following: (1) Void holes of 8-¾- and 12-¼-inch diameters in burn cuts in limestone will pull 20 feet with proper blast design, (2) half-second delays are too slow for use in burn blasting blocky or bedded deposits because they tend to cause cutoffs between relief holes, and (3) visual inspection of the blast zones indicated that, except for the immediate vicinity of the blasts, fracturing occurred along preexisting joint and bedding planes in the limestone.

A new method of hard rock excavation employing high-velocity, smooth bore, 90- and 105-millimeter cannons firing solid concrete projectiles weighing 8 to 12 pounds was successfully demonstrated. This work demonstrated the rock breaking effectiveness of high-velocity projectile impact, the control of tunnel contour while minimizing damage and overbreak, and the development of a silencer able to deenergize and control muzzle blast. It was demonstrated that this is also a viable method for drilling holes, carving out a surface cut, and breaking large boulders.

Metallurgy.—The general objective of the metallurgy program is to provide, through research and development, the scientific and technical information necessary to encourage and stimulate the nonfuel minerals industry to make the expeditious advances in technology that will encourage the industry to produce an adequate supply of mineral raw materials at acceptable material and energy costs, and with a minimum of waste and environmental degradation.

In 1974, the Bureau of Mines operated a miniplant for demonstrating and evaluating processes for the recovery of alumina from domestic nonbauxitic resources. This cooperative project, which had the support and advice of eight domestic and two foreign aluminum companies, was considering five potential processes. Modifications were made to the operating nitric acid miniplant, and construction and installation of the hydrochloric acid miniplant was being completed. Additional installations to evaluate the sulfurous acid, lime-soda sinter, and alunite processes were planned. In other alumina-related work, the chlorination of calcined clay below 1,000°C was found to be too slow and complicated by the production of silicon, iron, and titanium chloride. Higher temperatures produced little improvement in rate and led to severe equipment problems.

An impending worldwide shortage of rutile has led to Bureau-sponsored studies aimed at developing methods to convert domestic ilmenite ($FeTiO_3$) into feed material suitable for pigment-grade titania or titanium metal. Smelting with soda ash recovers over 95% of the iron in ilmenite as high-quality pig iron. The slag is leached to produce a low-iron sodium titanate midproduct that can be used as a superior feed for the sulfate process to yield titania pigment. Mineral synthesis techniques were applied to Idaho and New York ilmenites to yield a high-purity rutile with titanium recoveries ranging from 82% to 96%. Another potential process that was investigated utilized removal of iron by smelting, followed by carbiding the titanium in the slag and chlorination of the carbide. More than 85% of the titanium in ilmenite or perovskite ($CaTiO_3$) was recovered as high-purity titanium tetrachloride.

Increasing attention was being devoted to improving the effectiveness with which energy is used in metallurgical processing. As a basis for this research and development, energy use patterns in the metallurgical and nonmetallic mineral processing industries were the focus of a study funded by the Bureau of Mines. An improved hooding system, which limits the entrance of tempering air into the Bureau-developed continuous ferrous scrap preheater for steelmaking, was developed. The new system produces comparable-ingot-quality carbon steels with lower heat times and lower energy consumption, as compared with conventional batch melting and refining. The thermal efficiency of electric furnace steelmaking also was improved through demonstration of continuous charging and preheating of charge materials. Substitution of alternate fuels for natural gas for indurating iron ore pellets obtained from taconites was under investigation also. Work completed to date in an 800-pound-per-hour, continuous-travelling-grate rotary kiln system has demonstrated the feasibility of firing pellets using Kentucky bituminous coal, Montana subbituminous coal, and a North Dakota lignite as fuels.

The Bureau of Mines developed a process for producing blister copper in a submerged arc furnace from roasted sulfide concentrates. Cement copper also can be processed by electric arc furnace smelting to recover over 98% of the contained copper as blister. Prompt recovery of copper values from mine strip waste may be obtained by sizing the waste and leaching only the coarse fraction. Studies showed that the recovery of copper from copper mining waste could be substantially increased by using oxygen to stimulate the leaching. Progress in the high-current-density electrodeposition of copper in a channel flow-through cell showed that high-quality coherent desposits may be obtained at 300 ampere per square foot. Another potential resource of copper is the Duluth gabbro complex which also contains substantial amounts of nickel. Studies of optimum processes for recovering values from this important national resource were continuing. Process developments were continuing also on the recovery of nickel from the lateritic ores of southern Oregon.

Construction of a commercial flotation mill based on a Bureau-developed potash flotation method for the production of potassium concentrates from low-grade Great Salt Lake evaporites was started. The process produces concentrates containing 14% K_2O from crude salts having a 6% or less K_2O content with 85% of the halite content of the salts being rejected. The new process permits the utilization of low-grade evaporites which previously were returned to the Great Salt Lake. The Bureau continued its cooperative program of testing clay specimens submitted by State geologists. Approximately 500 samples from 23 States were evaluated in 1974. The testing program identifies sources of raw materials for products used by local construction industries.

The Bureau of Mines assisted ERDA by developing improved materials for use in ERDA's Synthane plant, which converts coal to high-Btu gas. Materials were being prepared and tested for use as valve seats, ceramic liners, and Raney nickel catalyst structures. A catalytic conversion step is used to upgrade the low-Btu gas produced by most coal gasification processes into high-Btu, pipeline-quality fuel. The catalyst, known as Raney nickel, is derived from a brittle aluminum-nickel alloy which is applied to the reactor surfaces by flame spraying. This technique is slow and tedious because the only available feed material has been a fabricated plastic rod containing small particles of the alloy. A much improved form of feedstock has been made by using a novel but simple casting technique which produces long, solid rods of the alloy. The rate of flame spraying is 15 times faster with the solid rods than with the conventional feed material.

A method for the production of mischmetal, developed by the Bureau of Mines, has been adopted by industry. The new method, which permits the electrolysis of rare-earth oxides in a rare-earth fluoride bath, is now a viable alternative to the traditional electrolysis of rare-earth chlorides. Small quantities of mischmetal impart superior toughness and bendability to high-strength, low-alloy steels for pipeline and automotive applications.

In less than 2 years the Bureau made notable progress and achieved national recognition in research concerned with solving severe corrosion and scaling problems associated with energy and mineral recovery from geothermal fluids. A variety of select materials, provided by industry, State, and Federal organizations, have been tested in-line at one test well site to determine which metals and alloys will perform satisfactorily in the harsh brine environment. Plans for cooperative geothermal work with the Bureau of Reclamation were underway to make in-line tests at a Bureau of Reclamation test facility.

To provide a process suitable for the production of lead metal by small-volume producers and avoid generating noxious sulfur dioxide, the Bureau was making a feasibility study of winning lead metal by low-temperature, molten-salt lead chloride electrolysis. An aqueous chlorine leach procedure for treating sulfide concentrates is effective in extracting the values. Lead is recovered as the chloride from the leach solution and dried prior to molten salt electrolysis. Zinc also may be recovered as the chloride, and an evaluation of cell design for electrowinning zinc from the chloride was being made. Chlorine, produced in the electrolysis, may be recycled to the concentrate treatment step. The process avoids environmental problems associated with the production of sulfur dioxide.

Research on soldering aluminum has resulted in a method for repairing aluminum air conditioning condensers. Until development of the new method, defective condensers had to be discarded. In the new approach, interfacial corrosion at the solder joint is prevented by using a graded seal of aluminum, zinc, nickel, copper, and tin-lead soldler.

Carbon-in-pulp cyanidation was demonstrated by the Bureau to be useful for recovering silver from low-grade ores and mine wastes. The silver is stripped from the activated carbon, after it is separated from the pulp, by a newly developed alcohol elution technique. After the silver is electrowon from the carbon effluent, the effluent is recycled. Pilot plant work has demonstrated that about 70% of the silver can be recovered from low-grade mill tailings. Information concerning the use of carbon-in-pulp cyanidation is being transferred to small mine operators.

Research in noise damping has developed procedures for reducing noise by 15 dbA during the chipping of castings. Improved muffler design and the use of noise damping alloys also have proven to be effective in significantly reducing underground drilling noise generated by pneumatic rock drills.

Resource Recovery and Pollution Abatement.—The Bureau, in cooperation with the Florida Phosphate Council, continued its efforts to dewater Florida phosphate slimes. The slimes require extensive holding ponds for storage. Attapulgite ($(\mathrm{Mg,Al})_2\mathrm{Si}_4\mathrm{O}_{10}(\mathrm{OH})\cdot 4\mathrm{H}_2\mathrm{O}$) has been identified as a major factor in preventing easy dewatering. Efforts continued to scale up a Bureau-developed settling technique which relies on the slow movement of screens through the slime, compacting the solids, and collecting clear supernatant water above the screen.

Investigations of the utilization of stainless steel wastes such as dust, scale, and swarf have shown that pelletized mixtures can be melted with scrap using ferrosilicon as the reductant in an electric arc furnace to obtain nearly complete recovery of the iron, chromium, nickel, and manganese. Processes also were developed for recycling alkaline cyanide and acid electroplating wastes, spent etching solutions, electrochemical machining sludges, and electroplating sludges. Pelletized mixtures of steelmaking flue dust and coke breeze were tested in a continuous processing furnace to recover zinc metal. The residue contains 65% iron and manganese. Studies were being directed to upgrade the residue so that it will be satisfactory for recycling to an electric furnace.

A simple mineral processing technique was applied by the Bureau to recover sand and brass from used brass foundry molding sands. The procedure has broad application in the brass foundry industry and has been adopted by one foundry. Substantially all of the brass and sand are recovered. In addition to recovery of brass valued at about $60 per ton of mold sand treated, the sand is recycled at an estimated gross savings of $19 per ton.

Asphalt-sand paving material with sulfur additions, developed by the Bureau, was undergoing road testing at Boulder City, Nev. It was found that sulfur can substitute for as much as 75 volume-percent of the binder. In addition to reducing asphalt requirements, the substitution of sulfur allows greater design latitude owing to greater stability under heavy traffic conditions.

In cooperation with a secondary copper producer, a simple mineral processing scheme was developed for recovering copper from copper blast furnace slags generated during smelting of scrap copper. These slags, which contained as much as 100 pounds of copper per ton, were being discarded. Based on the result of this research, the company planned to install a full-scale plant to treat slag from its blast furnace operations.

One phase of the Bureau's research on the abatement of pollution by the minerals industry was directed toward developing low-cost and effective methods for decontaminating, purifying, and conserving mineral processing waste waters. Under this program, a simple procedure was devised which removes trace quantities of selenium, an extremely toxic element, from zinc production plant waste scrubber water. The process was being tested in a continuous process development unit at a zinc plant to obtain engineering and cost data preparatory to installation of units to treat all of the plant water.

The Bureau continued to be in the forefront of research in developing methods for recovering useful components from scrap automobiles. A method was devised in cooperation with two major auto companies to recover polyurethane, which is being used in increasing quantities in newer model autos for padding, seat cushions, and insulation. The use of polyurethane by the auto industry was expected to increase to 600 million pounds in 1975. This is triple the amount used in 1971. Reclaiming the plastic will become increasingly important as more recent model autos are junked, requiring refinement of the technology already developed. Not only will such recovery systems alleviate disposal problems, but valuable petroleum raw materials from which plastics are made will be conserved. Progress was made on upgrading reject scrap from automobile shredders. A water elutriation procedure was developed which yields a 99% metal product representing a recovery of 95% to 99% of the metal content.

A new method for processing lead battery scrap was developed that eliminated nearly all of the sulfur dioxide emission produced when normal reverberatory or blast furnace methods are used. The patented method employs a hydrometallurgical step to convert lead sulfate to lead oxide and $CaSO_4$. The lead oxide is then reduced by carbon, and the $CaSO_4$ is removed with a flux. Lead recoveries were as high as 97%. This promising nonpolluting method has been adopted by industry.

Coal.—In 1974, the Bureau of Mines continued to be deeply involved in its effort to solve the complex energy-environment enigma. The economic production of gasoline and fuels from coal-derived synthesis gas (hydrogen-carbon monoxide mixtures) will be a useful alternative to increased petroleum imports. Developmental work on the conversion of coal to synthetic natural gas (SNG) continued in a small pilot plant as well as in bench-scale units. Studies showed that the production of coal gasifiers may be significantly increased by the addition of suitable materials to the coal in small amounts. The Bureau's effort to develop a process for converting coals into low-sulfur, low ash fuel oils (SYNTHOIL) also continued in 1974. This process uses a turbulent-flow, packed-bed reactor for liquefaction and catalytic hydrodesulfurization of coal. The cost of the fuel compares with that of fuels derived from petroleum. The HYDRANE process, in which coal is reacted with hydrogen to produce methane, has the advantages of utilizing agglomerated coals without treatment as feedstock and also has a high gas output per million Btu of energy in the coal. The overall yields of methane were similar to the calculated design values needed for large-scale operation.

The COSTEAM process converts low-rank coals such as lignite to low-sulfur fuel oil. The oil resembles a heavy No. 6 fuel and has a heating value of about 4,000 Btu per pound. A revolutionary step in coal technology — (UNDERGROUND COAL GASIFICATION) which induces the partial combustion of coal in place to produce a gas that could be burned to produce electricity—was taken by the Bureau in 1974. Successful development of such technology could replace underground mining and thus eliminate the problems associated with it.

In the Bureau's six energy research facilities throughout the United States, additional processes were investigated "to develop effective means that will increase the availability and improve the utilization of the Nation's energy resources at reasonable costs and in a manner that will attain desirable social and environmental improvements." As mentioned previously, Bureau energy research was transferred to ERDA.

Petroleum.—The Bureau's Project Halo was directed at correlating observed gamma-radiation anomalies at the surface of the earth with the presence of hydrocarbon deposits at depth, to determine whether the presence of the anomalies can be used as a technique for petroleum exploration The present work on the project involves sorting different variables to determine which have an immediate and measurable effect upon observed anomalous patterns.

A project involving solvent-extraction and distillation procedures produced experimental quantities of high-quality lubricants from waste crankcase oils, which have good oxidation stability, pass wear and corrosion tests, and meet viscosity requirements. Furthermore, production of potentially polluting byproducts was lower.

In June 1974, the Bureau awarded a multimillion-dollar contract to Cities Service Oil Co. to demonstrate a micellar-polymer flooding technique for tertiary oil recovery. Surfactants and cosurfactants form the active part of micellar fluid; the other part of the fluid is composed of dilute salt water and sometimes crude or refined oil. The final driving fluid will be water.

The Bureau's SolFrac process, which stimulates heavy oil production, uses an explosive fracturing-solvent injection method; the result is the recovery of viscous crude oil. By June 1974, five wells were drilled and shot with explosives, producing 1,151 barrels of solvent-oil mixture containing 91.4 barrels of crude oil.

Another method to recover heavy oil is a process whereby the oil is diluted with a solvent and flows more easily to the producing well. This technological innovation will make possible the recovery of large quantities of oil in the United States, especially California, that cannot be recovered with present technology. The profitability of this method has yet to be proven, however.

Fuel economy in automobiles can be improved by up to 25% using advanced lean combustion engines, including diesels. These innovations are still at the experimental level. The improvement in fuel economy is a result of a compromise between the most stringent proposed standards for emission levels and the 1974 standards. Other experiments suggest that if the most stringent standards are implemented, fuel economy will be further eroded by 1% to 15% from 1974 levels. In terms of the automobiles of the 1960's, it will be a decrease in fuel economy of 30%. Other tests showed that fuel addiives that maintain engine cleanliness and conserve energy have no deleterious effect on the atmosphere.

Oil Shale.—Investigations on the feasibility of producing shale oil by in situ retorting continued in laboratory, pilot plant, and field-scale experiments. The successful development of this process could add significantly to our liquid fuel supplies. Furthermore, this process may prove applicable to deposits of shale that vary in thickness, grade, and depth of burial, many of which may not be readily amenable to mining and above ground retorting. The effect of using steam during retorting was studied, using a 10-ton-capacity batch retort. The results showed that the steam lowered maximum bed temperatures and improved the quality of the offgas, but slightly decreased the recovery of oil.

Other Bureau investigations concerned the occurrence, nature, and evaluation of oil shale deposits in the Green River Formation in Colorado, Utah, and Wyoming. Information was gathered on the extent of these deposits, about variations in oil potential and other characteristics at various locations, and on the possibilities of concurrent production of both minerals and fuels. The Bureau's oil yield data and geology of a part of the Kinney Rim of the Washakie Basin in Wyoming were used to evaluate lease tracts for the production of shale oil.

A Bureau program showed that even though shale oil differs from petroleum, it can be modified to be amenable to commonly practiced petroleum-refining operations. The reduction of sulfur, nitrogen, and oxygen contents of in situ crude shale oils is the primary goal of oil shale refining. This will minimize the pollution of the atmosphere when the final products are used as fuels. Furthermore, the work is intended to provide guidelines in selecting catalysts and operating conditions for future industrial processing of shale oil.

Economic Analysis.—Bureau of Mines economic research activities in 1974 continued to concentrate on economic factors that affect the mineral industries. The purpose of the research was to provide decisionmakers with information and up-to-date analyses of the economic situation, future trends, alternative courses of action, and the impact of choosing any of the alternatives. The economic analysis program attempted to produce the general methodology needed for such studies, as well as information relevant to problem solving in the field of mineral economics. Major long-term research projects in which the Bureau's Division of Economic Analysis was involved included the study and forecasting of demand, supply, and productivity; financial analysis; mineral taxation; waste recycling; input-output analysis; the study of mineral transportation; measures of economic activities stimulated by mineral industries; index numbers; international trade; a weekly price report on minerals and fuels; and a monthly report highlighting major mineral commodities. Some of the short-term projects undertaken in 1974 involved a study of the economic significance of the Florida phosphate industry; assisting in the establishment of an Office of Economic Analysis within the Puerto Rican Department of Natural Resources; a research paper on foreign investment and the changing pattern of mineral supplies; commenting on proposed legislation; a study to estimate the impact of eliminating the percentage depletion allowance on domestic hard minerals; a special detail to the Office of Territories to initiate the preparation of an environmental impact statement on a deepwater port in the Virgin Islands; reviewing the framework to be used as a guideline for the working groups of Project Independence; and monitoring and reporting to governmental policymakers the economic impact of the coal strike.

Helium.—Helium research was directed at production, analytical methods and techniques relating to helium in natural gas, and impurities in purified helium. The Bureau developed a higher grade helium product which provided for a growing need for helium as a heat transfer medium in high-temperature gas reactors (HTGR). Normally high-purity helium contains 100 to 200 parts per billion (ppb) helium-3. Helium-3 can become radioactive in the presence of a radioactive atmosphere. Pure helium-4 is not affected by the radioactivity. The higher grade product developed contains about 20 ppb helium-3; however, 1 ppb helium-3 can be obtained at a reduced production rate and a reduced system efficiency. The Bureau has also developed mass spectrometry techniques to determine the concentration of helium-3 in a sample to a minimum of 1 ppb. This can be used to monitor the Bureau's production of the higher grade helium product containing less than 20 ppb helium-3.

LEGISLATION AND GOVERNMENT PROGRAMS

New and continuing Federal activities dealing with economic stabilization, energy, the environment, resources, and international trade had significant impacts on the minerals sector. The Government continued to use monetary and fiscal tools to fight inflation and promote a stable economy. The Economic Stabilization Act Amendments of 1971 expired early in the year. This act had been the basis for price controls. Since continued use of price controls was not anticipated, the act was allowed to expire.

Energy continued to be a major concern of the Government during 1974. The Arab oil embargo was in effect as the year began. After this embargo was lifted, the price of foreign oil was well above the preembargo level. It was determined that the United States should become more self-sufficient in energy, to offset balance of payment problems and the vulnerability to embargoes. A number of measures to achieve this goal were put forth. These included measures to promote standby domestic capacity and strategic oil reserves for an emergency; to reduce consumption; and to increase production from conventional and new energy resources.

Activities designed to improve the environment, conserve our natural resources, promote public safety, regulate international trade, etc., continued to be important.

Mineral-related legislation enacted into law during 1974 dealt with energy, environmental quality, water, public lands, health and safety, gold and silver, tariffs, and other relevant subjects. Energy was the subject of a large number of laws. Two Federal energy agencies were established. Public Law 93–275 created the Federal Energy Administration (FEA) to deal with energy problems, and Public Law 93–438 consolidated certain Federal energy research functions into ERDA. Three laws were concerned with atomic energy: Public Law 93–377 amended the laws regulating atomic materials, Public Law 93–485 gave the Congress the power to concur in or disapprove international agreements for cooperation with regard to certain nuclear technology, and Public Law 93–514 provided that the Joint Committee on Atomic Energy make an annual report to the Congress on available nuclear information. Three laws passed by Congress promoted energy research and development. Public Law 93–410 was designed to promote the development of geothermal energy, Public Law 93–473 was designed to promote the development of solar energy, and Public Law 93–577 provided Federal support for programs of research and development of fuels and energy.

Environmental quality was also the subject of a significant number of laws. Five laws dealt with the marine environment: Public Law 93–248 implemented the International Convention Relating to Intervention on the High Seas in Cases of Oil Pollution Casualties, Public Law 93–254 implemented the Convention on the Prevention of Marine Pollution by Dumping of Wastes and Other Matter, Public Law 93–472 authorized money for fiscal year 1975 for the implementation of the Marine Protection, Research, and Sanctuaries Act, Public Law 93–513 assured compensation for damages caused by nuclear incidents involving the nuclear reactor of a U.S. warship, and Public Law 93–524 determined that spaces in vessels used for waste materials should be deducted from gross tonnage to determine net tonnage. Public Law 93–278 extended the Environmental Education Act for 3 years, and Public Law 93–319 dealt with the burning of coal at powerplants. Public Law 93–633, which strengthened the laws governing the transportation of hazardous materials, was not signed into law until January 3, 1975. A listing of mineral-related Federal legislation signed into law during 1974 follows:

Public Law (P.L.)	Description	Signed into law
Energy:		
93–275	To create a new Federal Energy Administration.	May 7
93–377	Amending in several respects the atomic energy laws.	Aug. 17
93–410	Authorizing guaranteed loans to finance commercial ventures in the field of geothermal energy, and to coordinate Federal activities in the development of geothermal energy.	Sept. 3
93–438	To consolidate certain functions of Government in a new Energy Research and Development Administration.	Oct. 11

Public Law (P.L.)	Description	Signed into law
93-473	Authorizing funds for Federal programs for research and development of solar energy as a practical means for heating and cooling.	Oct. 26
93-485	Enabling Congress to concur in or disapprove international agreements for cooperation with regard to certain nuclear technology.	Oct. 26
93-511	To extend until August 31, 1975, the Emergency Petroleum Allocation Act.	Dec. 5
93-514	Providing that the Joint Committee on Atomic Energy make an annual report to the Congress on available nuclear information.	Dec. 6
93-577	Providing Federal support for programs of research and development of fuels and energy.	Dec. 31
Environmental quality:		
93-248	Implementing the International Convention Relating to Intervention on the High Seas in Cases of Oil Pollution Casualties, 1969 (Ex. G, 91st Cong., 2d Sess.).	Feb. 5
93-254	To provide for the implementation of the Convention on the Prevention of Marine Pollution by Dumping of Wastes and Other Matter (Ex. C, 93d Cong., 1st Sess.).	Mar. 22
93-278	Extending for 3 years the Environmental Education Act and authorizing funds therefore.	May 10
93-319	Proposed Energy Supply and Environmental Coordination Act of 1974.	June 22
93-472	Authorizing $5.5 million for fiscal year 1975 for the implementation of the Marine Protection, Research and Sanctuaries Act.	Oct. 26
93-513	Assuring compensation for damages caused by nuclear incidents involving the nuclear reactor of a U.S. warship.	Dec. 6
93-524	To deduct from gross tonnage, in determining net tonnage, those spaces in vessels used for waste materials.	Dec. 18
Water resources:		
93-304	Authorizing $5.6 million for U.S. participation in the International Ocean Exposition '75.	June 8
Public lands:		
93-535	To establish the Cascade Head Scenic-Research Area in Oregon.	Dec. 22
Health and safety:		
93-403	Authorizing funds to extend provisions of the Natural Gas Pipeline Safety Act of 1968.	Aug. 30
Gold and silver:		
93-373	To provide for increased participation by the United States in the International Development Association and to permit U.S. citizens to purchase, hold, sell or otherwise deal with gold in the United States or abroad.	Aug. 14
93-463	To strengthen the regulation of futures trading by bringing all agricultural and other commodities traded on exchanges under regulation.	Oct. 23
Tariffs and duties:		
93-470	Providing temporary suspension of duty on synthetic rutile.	Oct. 26
93-497	Continuing suspension of duty on certain forms of copper.	Oct. 29
Miscellaneous:		
93-426	To amend and extend the Defense Production Act.	Sept. 30

The acquisition cost of strategic and critical materials, as of December 31, 1974, totaled $2.7 billion with a market value of $5.7 billion. Materials in these Government inventories with a market value of $6.8 billion were considered to be in excess of stockpile needs. During 1974 the Government disposed of $1.4 billion worth of mineral commodities, 75% more than in 1973. Commodities with greatest sales value consisted of copper with $450 million, tin with $197 million, zinc with $181 million, and aluminum with $177 million. Commodities with sales value of less than $10,000 consisted of antimony, mica (phlogopite block), and talc.

WORLD REVIEW

World Economy.—During 1974, sharp worldwide increases in the price of energy products, food, and other basic materials created new and large payment imbalances for most countries. Consumer prices in industrialized countries rose by about 14%, which was nearly double the average rise in 1972–73. Adding to the pressures of these price increases, world production of foods fell as demand rose.

Early in 1974, policymakers of different industrialized countries were faced with the problems involved in dealing with inflation and a stagnant economy. Real GNP in the industrialized countries, excluding the United States, rose slightly over 1%. The average of the GNP deflators for these countries increased more than 12% compared with an almost 4% annual average increase for the past decade.

In general, the international financial and economic system seemed to adjust well to the disturbances of 1974. Countries refrained from shifting their domestic problems to other countries which resulted in a shrinkage in world trade. Thus the international monetary system was able to cope with the different rates of inflation and the higher energy prices. The Eurodollar market came into public focus as an important means of "recycling petrodollars" by being a channel for the flow of funds from the oil-exporting countries to borrowers.

World Production.—The United Nations (UN) indexes of world mineral industry production (1970=100) increased 4 index points to 118 for the extractive industries during 1974. The metal mining index increased 2 points to 110, the coal index remained unchanged at 96, and the crude petroleum and natural gas index increased 6 points to 127. The mineral processing industries indexes showed a 3-point increase to 122 for base metals, a 3-point increase to 127 for nonmetallic minerals, and a 5-point increase to 134 for chemicals, petroleum, and coal products. Overall industrial production as measured by the UN index rose 5 points to 127 for 1974.

World Trade.—The value of world export trade in all commodities increased almost 38% to $572.7 billion in 1973 (latest data available). For mineral commodities the figure increased almost 43% to $123.9 billion. Metal trade increased over 43% to $56.7 billion; within this group, all ores, concentrates and scrap trade, iron and steel trade, and nonferrous metal trade all followed this same trend. Crude nonmetal trade increased over 30% to $4.2 billion, and trade in mineral fuels increased over 43% to $63.1 billion.

World Prices.—Mineral commodity export prices increased by a magnitude of three during 1974. In the metal ores sector, the price index increased over one-third to 216 index points, and the fuel price index almost tripled to 553 index points. The index for all crude minerals increased almost 164% to 447 index points. Total minerals price increases were stronger in developing areas than in developed areas, although the index for nonferrous base metal prices increased about the same in both areas.

Nonmetals	101	88	94	91	100
Total	106	103	95	85	100

p Preliminary.

Table 9.—Physical stocks of mineral energy resources and related products at yearend

(Producers' stocks, unless otherwise indicated)

Fuel	1970	1971	1972	1973	1974 [p]
Coal and related products:					
Bituminous coal and lignite [1] short tons	92,275,000	89,985,000	[r] 116,500,000	103,022,000	95,572,000
Coke do	4,113,000	3,510,000	2,941,000	1,184,000	935,000
Petroleum and related products:					
Carbon black thousand pounds	296,087	296,028	237,695	[2] 230,825	293,903
Natural gasoline, plant condensates, and isopentane thousand barrels	7,046	6,176	6,075	7,835	7,550
Crude petroleum and petroleum products [3] do	1,010,815	1,037,771	952,904	1,000,472	1,066,096
Crude petroleum do	276,367	259,648	246,395	242,395	265,020
Gasoline do	214,348	223,771	217,149	209,395	218,346
Special naphthas do	6,193	5,384	5,232	4,514	5,716
Liquefied gases [4] do	67,043	94,713	85,717	83,086	97,956
Distillate fuel oil do	195,271	190,622	154,319	196,421	200,029
Residual fuel oil do	53,994	59,681	55,216	53,480	59,694
Petroleum asphalt do	15,779	21,202	21,636	15,024	21,370
Other products do	181,820	182,750	167,240	196,074	197,965
Natural gas [5] billion cubic feet	3,207	3,523	3,523	3,906	3,969

[p] Preliminary. [r] Revised.

[1] Industrial consumers and retail yards.

[2] Corrected figure.

[3] Includes natural gas liquids.

[4] Includes ethane.

Table 11.—Value of selected minerals and mineral products imported and exported by the United States in 1974, by commodity group and commodity [1]

(Thousand dollars)

SITC code [2]		Exports	Imports
	Minerals, nonmetallic (crude):		
271	Fertilizers, crude	257,117	25,247
273	Stone, sand, and gravel	30,095	27,745
274	Sulfur and unroasted iron pyrites	95,727	51,383
275	Natural abrasives (including industrial diamonds)	64,806	65,884
276	Other crude minerals	216,920	267,446
	Total [3]	664,666	487,706
	Metals (crude and scrap):		
281	Iron ore and concentrates	35,148	696,298
282	Iron and steel scrap	848,744	33,669
283	Ores and concentrates of nonferrous base metals	226,955	690,785
284	Nonferrous metal scrap	295,021	205,230
285	Platinum and platinum-group metal ores and concentrates	68,853	211,961
286	Uranium and thorium ores and concentrates	270	200
	Total [3]	1,474,992	1,838,145
	Mineral energy resources and related products:		
321	Coal, coke, and briquets (including peat)	2,487,231	274,365
331	Petroleum, crude and partly refined	13,565	16,482,024
332	Petroleum products, except chemicals	778,090	7,728,118
341	Gas, natural and manufactured	163,476	865,568
	Total [3]	3,442,362	25,350,076
	Chemicals:		
	Inorganic chemicals:		
513	Elements oxides, and halogen salts	507,825	605,677
514	Other inorganic chemicals	326,895	128,144
515	Radioactive and associated materials except uranium and thorium	215,124	130,038
521	Mineral tar, crude chemicals from coal, petroleum, and natural gas	83,797	10,071
	Total [3]	1,133,641	873,930
	Minerals, nonmetallic (manufactured):		
661	Lime, cement, and fabricated building material, except glass and clay	39,808	155,845
662	Clay and refractory construction materials	116,769	82,349
663	Mineral manufactures, not elsewhere specified	170,415	78,651
	Total	326,992	316,845
	Metals (manufactured):		
671	Pig iron, spiegeleisen, sponge iron, iron and steel powder and shot, and ferroalloys	60,703	391,912
672	Iron or steel ingots and other primary forms	187,564	42,978
673	Iron or steel bars, rods, angles, shapes, and sections	357,020	1,545,209
674	Iron or steel universals, plates, or sheets	687,022	2,254,049
675	Iron or steel hoops and strips	141,895	76,239
676	Iron or steel rails and railway track construction materials	40,618	12,199
677	Iron or steel wire (excluding wire rod)	33,553	307,110
678	Iron or steel tubes, pipes, and fittings	852,318	751,239
679	Iron or steel castings or forgings, unworked	199,559	24,391
681	Silver, platinum, and platinum-group metals	199,018	882,573
682	Copper and copper alloys	414,939	1,190,371
683	Nickel and nickel alloys	114,110	493,818
684	Aluminum and aluminum alloys	477,960	382,494
685	Lead and lead alloys	32,685	58,163
686	Zinc and zinc alloys	47,697	458,656
687	Tin and tin alloys	50,925	295,183
688	Uranium and thorium metals and alloys	322	50
689	Miscellaneous nonferrous base metals	162,053	163,511
	Total [3]	4,059,962	9,330,145
	Grand total	11,102,615	38,146,847

[1] Data in this table are for the indicated SITC numbers only, and therefore may not correspond to the figures classified by commodity in the "Statistical Summary" chapter of this volume.

[2] Standard Industrial Trade Classification.

[3] Data may not to totals shown because of independent rounding.

Table 14.—Consumption of major mineral products, mineral fuels, and electricity, 1973, 1974, and projections

Commodity	1973	1974 [p]	2000
MINERAL PRODUCTS			
Ferrous metals:			
Iron ore ... thousand long tons	146,922	188,160	NA
Iron content ... thousand short tons	102,000	[e] 95,900	NA
Raw steel (production) ... thousand short tons	150,799	145,720	NA
Chromite ores (gross weight):			
Metallurgical grade ... do	920	902	NA
Refractory grade ... do	261	294	NA
Chemical grade ... do	206	251	NA
Manganese ore (35% or more Mn) ... do	2,140	1,880	3,900
Molybdenum (Mo content) ... thousand pounds	57,049	68,476	188,000
Tungsten (W content) ... do	15,386	16,298	76,400
Nonferrous metals:			
Aluminum (apparent consumption) thousand short tons	6,507	6,294	28,400
Antimony, primary ... short tons	20,613	18,041	48,000
Copper, refined ... thousand short tons	2,437	2,194	7,100
Lead, primary and secondary ... do	1,541	1,599	2,730
Zinc, all classes ... do	1,932	1,678	3,090
Mercury, primary ... 76-pound flasks	54,283	59,479	102,000
Platinum-group metals ... thousand troy ounces	1,831	1,981	3,157
Silver (industrial consumption) ... do	196,386	177,015	420,000

p Preliminary. r Revised.

[1] Heat value employed for bituminous coal and lignite follow: 1970, 12,290 Btu per pound; 1971, 12,120 Btu; 1972, 12,025 Btu; 1973, 12,005 Btu; and 1974, 12,000 Btu.

[2] Heat values employed for crude petroleum is 5,800,000 Btu per barrel.

[3] Hydropower and nuclear power include installations owned by manufacturing plants and mines, as well as Government and privately owned public utilities. The fuel equivalent of hydropower and nuclear power is calculated from the kilowatt-hours produced, converted to theoretical energy resources inputs calculated from national average heat rates for fossil-fueled steam-electric plants provided by the Federal Power Commission using 10,494 Btu per net kilowatt-hour in 1970. The heat rate used for hydropower in 1971 is 10,478 Btu per net kilowatt-hour generated; in 1972, 10,379 Btu; and in 1973–74, 10,389 Btu. Energy inputs for nuclear power from 1971 through 1974 are converted at an average heat rate of 10,660 Btu per net kilowatt-hour based on information from the Energy Research and Development Administration.

p Preliminary.

[1] Heat values employed follow: Anthracite, 12,700 Btu per pound; and bituminous coal and lignite, weighted average British thermal units provided by the Division of Coal, 12,110 Btu per pound in 1970, 11,980 Btu per pound in 1971, 11,875 Btu per pound in 1972, 11,825 Btu per pound in 1973, and 11,800 Btu per pound in 1974. Weighted average Btu for petroleum products obtained by using 5,248,000 Btu per barrel for gasoline, 5,355,000 for naphtha-type jet fuel, 5,670,000 Btu for kerosine and kerosine-type jet fuel, 5,825,000 Btu for distillate, 6,287,000 Btu for residual, 6,065,000 Btu for lubricants 5,537,000 Btu for wax, 6,636,000 Btu for asphalt, and 5,796,000 Btu for miscellaneous. Natural gas, dry 1,031 Btu per cubic foot in 1970–71; 1,027 Btu in 1972; 1,021 Btu in 1973; and 1,024 Btu in 1974; natural gas liquids, weighted average British thermal units; natural gasoline and other products, 110,000 Btu per gallon; LP 95,500 Btu per gallon; ethane, 73,390 Btu per gallon, and plant condensate, 129,000 Btu per gallon beginning in 1973. Hydropower (adjusted for net imports of electricity) and nuclear power are derived from net electricity gentural gasoline and other products, 110,000 Btu per gallon; LPG 95,500 Btu per gallon; ethane, erated converted to theoretical energy resources input calculated from national average heat rates for fossil fueled steam-electric plants provided by the Federal Power Commission using 10,494 Btu kilowatt-hour generated 10,379 Btu in 1972, and 10,389 Btu in 1973 and 1974. Energy inputs for nuclear power from 1971 through 1974 are converted at an average heat rate of 10,660 Btu per net kilowatt-hour based on information from the Energy Research and Development Administration.

[2] Net imports of coke (2,262,000 tons in 1974). Remainder of coke consumption is accounted for in utilizing gross total Btu value of coal carbonized for coke.

[p] Preliminary. NA Not available.

[1] Includes use by producers for power and heat.

[2] Includes shipments to U.S. Armed Forces in West Germany.

[3] Except for small quantities used as raw material for coal chemicals, all anthractie is used for fuel and power.

[4] Data represent "retail deliveries to other consumers." These are mainly household and commercial users, with some unknown portion of use by small industries.

[5] Includes consumption by coke plants, steel and rolling mills, and other industrial uses. Adjusted to exclude coal equivalent of raw material use.

[6] Figures in parentheses are not added into totals.

[7] Includes bunkers and military transportation.

[8] Coal equivalent based on British thermal unit value of raw material consumption of coal chemicals listed.

[p]Preliminary. NA Not available. XX Not applicable.

[1] **Net imports of coke (2,262,000 tons in 1974). Remainder of coke consumption is accounted for in utilizing gross total Btu value of coal carbonized for** coke.

[2] Excludes natural gas liquids.

[3] Petroleum products including still gas, LRG, and natural gas liquids.

[4] Represents outputs of hydropower (adjusted for net imports or net exports) and nuclear power converted to theoretical energy inputs calculated from national average heat rates for fossil-fueled steam-electric plants provided by the Federal Power Commission using 10,494 Btu per net kilowatt-hour in 1970. Energy inputs for hydropower in 1971 are converted at an average heat rate of 10,478 Btu per net kilowatt-hour generated; 1972, 10,379 Btu; and 1973–74, 10,389 Btu. Energy inputs for nuclear power in 1971–74 are converted at an average heat rate of 10,660 Btu per net kilowatt-hour based on information from the Energy Research and Development Administration. Excludes inputs for power generated by nonutility fuel-burning plants which are included within the other consuming sectors.

[5] Gross energy is that contained in all types of commercial energy at the time it is incorporated in the economy, whether the energy is produced domestically or imported. Gross energy comprises inputs of primary fuels (or the derivatives) and outputs of hydropower and nuclear power energy converted to theoretical inputs. Gross energy includes energy used for production, processing, and transportation of energy proper.

[6] Utility electricity, generated and imported, distributed to the other consuming sectors as energy resource inputs. Distribution to sectors is based on sales reported in the annual issues of the Edison Electric Institute Yearbook. Conversion of electricity to energy equivalent by sectors was made at the value of contained energy corresponding to 100% efficiency using a theoretical rate of 3,412 Btu per kilowatt-hour.

[7] Energy resource inputs to final consuming sector, including direct fuels and electricity distributed.

[8] Includes bunkers and military uses.

[9] Data may not add to totals shown because of independent rounding.

Grand total	22,245,226	22,712.4	21,511,864	22,028.1

[p] Preliminary.

[1] Marketed production includes wet gas sold or consumed by producers, losses in transmission, producers' addition to storage, and increases in gas pipeline fill; excludes repressuring and quantities vented and flared. British thermal unit value of production is for wet gas prior to extraction of natural gas liquids. Higher Btu values assigned to extraction loss are reflected in value of natural gas liquids production for each year.

[2] Extraction loss from cycling plants represents offtake of natural gas for natural gas liquids as reported to the Bureau of Mines. Energy equivalent of extraction loss is based on annual outputs of natural gasoline and other products at 110,000 Btu per gallon, annual outputs of LPG at 95,500 Btu per gallon, and annual outputs of ethane at 73,390 Btu per gallon. (Prior to 1967, ethane production was included with LPG in converting to Btu value.) Beginning with 1973, energy equivalent for plant condensate is computed at 129,000 Btu per gallon.

[3] Includes "Other consumers" totals of 308,996 million cubic feet in 1973 and 292,708 million cubic feet in 1974.

[4] Includes transmission losses and unaccounted for of 195,863 million cubic feet in 1973 and 288,731 million cubic feet in 1974.

[5] Includes some fuel and power used by raw material industries.

[6] Estimated from partial data.

NOTE.—Conversion factors for dry gas are 1973, 1,021 Btu per cubic foot; 1974, 1,024 Btu per cubic foot.

Grand total	6,317.3	34,852.3	6,069.5	33,414.4

[p] Preliminary.

[1] Supply and demand for crude oil and petroleum products. Petroleum products refined and processed from crude oil, including still gas and liquefied refinery gas; also natural gas liquids transferred from natural gas.

[2] Btu values for natural gas liquids for each year shown are implicitly derived from weighted averages of major natural gas liquids, with natural gasoline and other products at 110,000 Btu per gallon, liquefied petroleum gases at 95,500 Btu per gallon, ethane at 73,390 Btu per gallon, and plant condensate at 129,000 Btu per gallon.

[3] Btu values for imported and exported refined products for each year shown are based on the average values of the respective products.

[4] Includes natural gas liquids other than those channeled into refinery input as follows: Petrochemical feedstocks, direct uses for fuel and power, and other uses.

[5] Includes bunkers and military transportation.

[6] Includes some fuel and power use by raw materials industries.

[p] Preliminary.

[1] Includes liquefied refinery gas and natural gas liquids.

[2] Includes bunkers, military transportation, and all military use of distillate and residual fuel oils.

[3] Includes secondary recovery of petroleum and agricultural uses.

[4] Includes some fuel and power used by raw materials industries.

[5] Lubricants are distributed on basis of data from Bureau of Census survey.

[6] Includes portions of petroleum coke estimated to be consumed in nonfuel uses.

[7] Includes ethane.

[8] Includes LPG for synthetic rubber.

p Preliminary. r Revised. NA Not available.

[1] Index of labor costs per unit of output: Iron ore and copper indexes are computed from data found in U.S. Department of Labor, Employment and Earnings and Wholesale Price Indexes. Bituminous coal index based upon net tons per man per day (see chapter on Bituminous Coal), and index of average earnings derived from Bureau of Labor Statistics data on hourly earnings; petroleum index based on barrels per year (see chapter on Petroleum), and Bureau of Employment Security data on total wages in petroleum production.

Index of value of product per man-period: Iron ore and copper indexes are computed from data found in U.S. Department of Labor, Employment and Earnings and Wholesale Price Indexes. Bituminous coal index based on net tons per man per day and mine value of production; petroleum index based on average employment and total value of production.

Index of labor costs per dollar of product: Iron ore and copper indexes are computed from data found in U.S. Department of Labor, Employment and Earnings and Wholesale Price Indexes. Bituminous coal index based on index of value per man per day and index of average earnings; petroleum index based on total value of production and total wages.

[2] Indexes are recoverable metal.

[3] Revisions are due to methodology change.

Table 56.—Summary of Government inventories of strategic and critical materials December 31, 1974

	Acquisition cost	Market value [1]
Total inventories in storage:		
National stockpile	$2,660,690,200	$5,741,697,000
Supplemental stockpile	1,129,556,800	2,080,416,200
Defense Production Act	346,133,800	214,899,700
Total on hand	4,136,380,800	8,037,012,900
Inventories within objective (in storage):		
Total on hand	528,342,700	1,189,629,000
Excess inventories in storage:		
Total on hand	3,608,038,100	6,847,383,900

[1] Market values are computed from prices at which similar materials are being traded; or in the absence of current trading, at an estimate of the price that would prevail in commercial markets. Prices used are unadjusted for normal premiums and discounts relating to contained qualities, or for inherent materials-handling allowances. Market values do not necessarily reflect the amount that would be realized at time of sale. The uncommitted excess excludes the unshipped sales; the inventories in storage include quantities that have been sold but not shipped.

r Revised.

[1] Data presented are for selected major commodity groups of the Standard International Trade Classification—Revised (SITC—R), and as such exclude some mineral commodities classified in that data array together with other (nonmineral) commodities. SITC—R categories included are as follows: Ores, concentrates, and scrap—SITC Division 28; iron and steel—SITC Division 67; nonferrous metals—SITC Division 68; nonmetals (crude only)—SITC Division 27; mineral fuels—SITC Division 3. Major items not included are the metals, metalloids, and metal oxides of SITC Group 513; mineral tar and crude chemicals from coal, petroleum, and natural gas of SITC Division 52; manufactured fertilizers of SITC Division 56; and nonmetallic mineral manufactures of SITC Groups 661, 662, 663, and 667.

Mining and Quarrying Trends in the Metal and Nonmetal Industries

By John L. Morning [1]

Although the value of metal and nonmetal mineral output from the Nation's mines increased by 21% during 1974, inflation pushed up mining costs and detracted from the apparent improved industry performance. As the year progressed, the industry was generally faced with declining profit margins resulting from increasing costs, declining revenues, and slackening demand. At yearend, the industry was increasing its reliance on new mining methods and improved technology to strengthen efficiency and production and to retain its profit margins.

Of the several significant technologic trends emerging in the mining industry during the year, one of the most notable was the constantly expanding application of computers in mining- and mineral-related operations from exploration through metallurgical process control. Computer programs were used to integrate data from geologic and mineral maps, accounting records, and price quotations to determine the economic value of various blocks of an ore body. Other uses for computers included reserve calculations, development drilling correlation, short- and long-range engineering planning, equipment use and maintenance scheduling, and spare parts control. In combination with digitizers and cathode-ray tubes (CRT), computers were increasingly used as drafting tools to help assess the impact of various alternatives in mine and pit design. In addition to the growing list of engineering applications, the use of computers continued to grow in the more familiar administrative areas such as accounting and payroll.

The use of remote sensing techniques drew increasing attention during the year in efforts to reduce exploration time and reach less accessible but promising areas of mineralization. Remote sensing is a multistage process in which sensors like the Earth Resources Technology Satellite (ERTS) and Side Looking Airborne Radar (SLAR) may be followed by medium- and large-scale aerial photography, infrared imagery, and airborne geophysical surveys in potentially mineral-rich areas. Data collected by the various processes are analyzed to determine if lithographic and structural features are indicative of possible mineralization.

The growing availability and use of automated large-diameter rotary drills continued as one of the most significant advances in drilling technology. These automated drills sense and respond to changing drill parameters, minimizing human errors and augmenting operator skill. Ultimately, per foot drilling costs are reduced, maintenance is minimized, and machine availability is increased.

In general, trends toward still larger and more automated equipment continued to dominate load and haul operations. The largest off-highway hauler manufactured, a 350-ton-capacity giant, was introduced during the year. Locomotives continued to increase in sophistication; some units were introduced with remote control. An electronic system for piloting driverless trucks was demonstrated and reported to be available commercially. The trend towards

---

[1] Supervisory physical scientist, Division of Ferrous Metals.

"bigger is better" was apparently slowing, however, in stripping equipment, and the 100-cubic-yard machine was gaining favor over larger equipment owing to the recurrence of problems with the oversize machinery.

In response to growing safety concerns, the largest manufacturer of nitroglycerin-based dynamite announced that it would remove these dynamites from its product lines by late 1976. A series of water gels employing less sensitive monomethylamine nitrate (MMAN) would be used as a substitute.

The shortage of fuels combined with sharply increased prices forced many companies to reexamine their energy needs and implement conservation and employee awareness programs in efforts to increase efficiency of energy use. The rising fuel and power prices were largely responsible for the introduction of numerous new energy-efficient products.

The Market Research Department of the Engineering and Mining Journal continued to make surveys on equipment in the minerals industry. Studies were published on both the coal and the metal and nonmetallic mining industries. One survey was the basis of three reports.[2] These studies presented information on quantity, size, and make of equipment and on replacement practices, future purchasing plans, and utilization.

Materials Handled.—Producers of metal and nonmetal minerals (excluding fuels) handled nearly 4.6 billion tons of ore and waste in 1974, down 2% from that of 1973 but 12% higher than in 1970 and 42% higher than in 1965. During the past 10 years, total material handled has grown at an annual rate of 3.6%.

Crude ore output in 1974 totaled 2,930 million tons, down 1% from that of 1973. This compares with 2,680 million tons produced in 1970, and 2,400 million tons produced in 1965. Crude ore output has grown at a rate of 2% annually during the last decade.

Quantities of waste mined to permit ore recovery totaled 1,650 million tons in 1974, down 3.5% from that of 1973. In 1965, waste material handled totaled 810 million tons, and in 1970, 1,410 million tons.

Copper and iron ore accounted for 85% of crude metal ore production, whereas phosphate rock, stone, and sand and gravel accounted for 94% of the nonmetal mine crude ore output.

Fourteen States each reported handling more than 100 million tons of total material, the same as in 1973. Arizona was the leader, followed by Florida and Minnesota. Nine States each reported over 100 million tons of crude ore production. Florida was the leader, followed by Minnesota and Arizona.

Eleven States indicated an increase in crude ore production, 17 States registered increased waste material handled, and 11 States indicated an increase in total material handled, compared with 1973 totals.

Magnitude of the Mining Industry.—Crude ore output in 1974 was reported from 14,990 mines and quarries, a 4% increase over the number reporting in 1973. In addition to these mines, 106 wells, ponds, or pumping operations produced sulfur, salt, lithium, boron, and magnesium. Crude ore production from individual mines ranged from about 1 to nearly 43 million tons, and total material handled ranged from about 1 to over 140 million tons.

Twenty-five mines reported over 10 million tons of crude ore production, four more than in 1973. Sand and gravel and phosphate rock mines accounted for the increase; sand and gravel mines increased from none to three, and phosphate rock mines rose from four to six. One copper mine dropped from the listing. In contrast, in 1966, 14 mines each had outputs of 10 million tons of crude ore. In terms of total material handled, 64 mines moved over 10 million tons of material each.

In terms of crude ore output, the 25 leading metal mines produced over 413 million tons of crude ore, a 7.8% decrease compared with that of 1973, and accounted for 66% of the total crude ore from metal mines. In terms of total material handled, the 25 leading metal mines moved 1,248 million tons of crude ore and waste, nearly 9% less than in 1973.

The 25 leading nonmetal mines, in terms of crude ore output, produced 199 million tons of crude ore, 6% more than in 1973, and accounted for nearly 9% of nonmetal crude ore production. The 25 leading nonmetal mines, in terms of total material handled, moved 419 million tons of material, 5% more than in 1973.

[2] Engineering and Mining Journal. Power Shovels. 1974, 25 pp.

Engineering and Mining Journal. Draglines. 1974, 25 pp.

Engineering and Mining Journal. Backhoes. 1974, 21 pp.

The Minntac mine of United States Steel Corp. continued to be the leader in crude metal ore production, followed by the Utah Copper mine of Kennecott Copper Corp. and the Erie Commercial mine of Pickands Mather & Co. In the top 25 listing, 6 mines reported an increase in crude ore production over that of 1973. The Lakehurst mine of American Smelting and Refining Co., producing ilmenite (titanium), approached operating capacity as output increased dramatically, and the mine made the top 25 listing for the first time.

The Suwannee phosphate rock mine of Occidental Petroleum Corp. returned to the top of the listing of 25 large nonmetallic mines in output of crude ore, a place that it held in 1972. The Calcite mine of United States Steel Corp. dropped to second place, followed by the Kingsford phosphate rock mine of International Minerals & Chemical Corp. In terms of total material handled for nonmetal mines, the leader was the Kingsford, followed by the Noralyn phosphate rock mine of International Minerals & Chemical Corp. and the Suwanne mine.

Large metal mines were located in 11 States with Arizona accounting for 8 mines, while large nonmetal mines were in 8 States with Florida accounting for 14.

Value of Principal Mineral Products.—When possible, the measurement of value used in table 4 is for crude ore treated or, in the case of some nonmetals, crude ore shipped. For some commodities the value is of beneficiated products. Values of some metals are assigned according to average selling price of refined metal.

Paralleling price increases resulting from inflation, the average value for all commodities increased 30% compared with that of 1973, rising from $2.94 per ton to $3.82 per ton. The average value for metals rose from $6.56 per ton in 1973 to $8.74 per ton in 1974, a 33% increase, while the average value for nonmetals increased from $1.96 per ton in 1973 to $2.48 per ton in 1974, a 27% increase. For comparison, the average value in 1966 for all commodities was $2.42 per ton; for metals, $5.14 per ton; and for nonmetals, $1.76 per ton.

The value of byproducts contributed to the overall value of a majority of the mineral commodities listed in table 4. Byproducts were a significant part of total value of metals such as bauxite, 22%; lead, 36%; silver, 14%; and zinc, 16%; and for nonmetals such as feldspar, 9%; and fluorspar, 18%. Except for salt and stone, value of byproducts at underground mines was substantially higher than at surface mines. Byproducts contributed 9% of the total value for metal ores and except for feldspar and fluorspar were insignificant for nonmetal minerals. Excluding the large-volume commodities of sand and gravel and stone, byproducts contributed 7% to the combined value of metal and nonmetal ores.

Comparison of Production From Surface and Underground Mines.—Surface mines contributed 94.5% of crude ore and 96% of total material handled in 1974. Both percentages were relatively unchanged from that of 1973, although there were minor shifts in percentages among the various commodities.

During the past 15 years, as indicated in table 1, total material handled during underground mining for metals decreased slightly, while that for nonmetal underground mining increased 50%. On balance, however, the percentage of all minerals mined by underground methods during this period of time has remained relatively constant.

Crude ore production at surface metal mines was nearly 7 times higher than that at underground metal mines, while total material handled was nearly 19 times higher at surface mines than at underground mines. Of the 2.7 billion tons of total material handled at nonmetal mines, nearly 97% was from surface operations.

Two metal commodities, lead and zinc, and three nonmetal commodities, potassium salts, sodium carbonate, and wollastonite, were mined entirely by underground methods. Crude ore production of 8 metals and 19 nonmetals came entirely from surface mines.

Underground mining accounted for a substantial percentage of crude ore output in four States: New Mexico (32%), Wyoming (32%), Colorado (31%), and Missouri (28%). No underground activity was reported in 16 States.

Ratio of Ore Treated to Marketable Prod-

uct.—The ratio of ore treated to marketable product, that is, the amount of ore processed to produce one unit of marketable product, varies with the type of mineral commodity. The ratio ultimately depends on the grade of ore treated and type of valuable mineral content. For many of the nonmetal commodities, the ratio is essentially 1 to 1. Ratios are significantly lower for underground mines than for surface mines for a specific commodity because of higher mining costs. The historical trend for most mineral commodities that are concentrated has been an increase in ratio as ores with smaller valuable mineral contents are mined and processed.

Exploration and Development.—Exploration and development work in 1974 increased 2%, compared with that of 1973, reversing the downward trend that had persisted since 1969. All of the increase came from increased development work at both metal and nonmetal mines. In contrast, exploration work was down slightly. Exploration work for nonmetals increased 34%, but failed to offset a 2% decrease in activity for metals.

Metal mines accounted for 69% of all development work and 96% of exploration activities. Development work at metal mines increased significantly primarily because of underground work at lead, zinc, and uranium mines, while increased development at nonmetal mines was the result of work conducted for sodium carbonate.

Exploration drilling footage decreased, except for diamond drilling footage which rose 15%. Exploration trenching footage more than doubled, compared with that of 1973; footage for metals increased 73%, and nonmetal footage increased nearly 6-fold.

As in 1973, four States reported over 1 million feet of exploration and development work. Wyoming led with 30% of total footage reported, followed by South Dakota (20%), New Mexico (19%), and Texas (11%). Exploration activity increased significantly in Utah and Tennessee for copper, in Idaho and Missouri for lead and zinc, in Minnesota for iron ore, and in Florida for phosphate rock. Rotary drilling accounted for 63% of all exploration footage, decreasing from 64% in 1973. Drifting and crosscutting accounted for 82% of the development work.

Stripping activity, primarily for copper in Arizona, accounted for 93% of total material produced in mine development in 1974. Other commodities that contributed significant material produced in development activities were iron ore in Minnesota and uranium in Wyoming. Michigan accounted for the largest quantity of total material produced in shaft and winze sinking, Arizona the largest quantity in raising, and Wyoming the largest quantity in drifting, crosscutting, or tunneling.

Explosives.—Apparent consumption of industrial explosives and blasting agents in the United States in 1974 was 2,762 million pounds, establishing a record high for the sixth consecutive year. However, consumption in the minerals industry decreased nearly 5%, compared with that of 1973. Overall, coal mining consumed 43%, quarrying 20%, and metal mining 17% of all industrial explosives and blasting agents.

Coal mining continued as the leading minerals industry consumer of permissible explosives (96% of the total), cylindrically packed blasting agents (87%), and other processed blasting agents and unprocessed ammonium nitrate (58%). The leading consumer of other high explosives was quarrying (65%) while metal mining was the chief user of water gels and slurries (62% of the total). Of the 2.2 million pounds of explosives consumed in the minerals industry, coal mining continued to be the leading user with 54% of the total, followed by quarrying and nonmetal mining (25%), and metal mining (21%). Although coal mining consumption increased about 1%, reduced usage in metal and nonmetal mining caused the lower usage in the minerals industry.

Kentucky, Pennsylvania, and Alabama continued to be the leading States in explosive consumption for coal mining, accounting for 47% of the total. Arizona and Minnesota were leading States for metal mining, accounting for 55% of the explosives used in metal mining. For nonmetal mining and quarrying, Pennsylvania, Illinois, and Ohio were leading States, accounting for 23% of explosives used in this category.

Beginning in 1972, the Institute of Makers of Explosives (IME) adopted new product classifications for industrial explosives and blasting agents. As a result, detailed data are not directly comparable with those of previous years.

More detailed explosives information is

published in the Annual Explosives issue, Mineral Industry Surveys, prepared by the Division of Nonmetallic Minerals, Minerals and Materials Supply/Demand Analysis, Bureau of Mines.

Statistical Summary

By Staff, Office of Technical Data Services

This chapter summarizes data on crude mineral production for the United States, its island possessions, and the Commonwealth of Puerto Rico. Included also are tables that show the principal mineral commodities exported from and imported into the United States, and that compare world and U.S. mineral production. The detailed data from which these tables were derived are contained in the individual commodity chapters of volume I and in the State chapters of volume II of this edition of the Minerals Yearbook.

Although crude mineral production may be measured at any of several stages of extraction and processing, the stage of measurement used in this chapter is what is normally termed "mine output." It usually refers to minerals or ores in the form in which they are first extracted from the ground, but customarily includes the product of auxiliary processing at or near the mines.

Because of inadequacies in the statistics available, some series deviate from the foregoing definition. In the cases of gold, silver, copper, lead, zinc and tin, the quantities are recorded on a mine basis (as the recoverable content of ore sold or treated). However the values assigned to these quantities are based on the average selling price of refined metal, not on the mine value. Mercury is measured as recovered metal and valued at the average New York price for the metal.

The weight or volume units shown are those customarily used in the particular industries producing the commodities. Values shown are in current dollars, with no adjustment made to compensate for changes in the purchasing power of the dollar.

Table 1.—Value of crude mineral production [1] in the United States, by mineral group
(Million dollars)

Year	Mineral fuels	Nonmetals except fuels	Metals	Total [2]
1970	20,152	5,712	3,928	29,792
1971	21,247	6,058	[r] 3,406	[r] 30,711
1972	22,061	6,482	3,642	32,185
1973	25,012	7,418	4,362	[r] 36,787
1974	40,937	8,682	5,552	55,172

[r] Revised.

[1] Production as measured by mine shipments, sales, or marketable production (including consumption by producers).

[2] Data may not add to totals shown because of independent rounding.

---

[e] Estimate. [r] Revised. NA Not available. XX Not applicable. W Withheld to avoid disclosing individual company confidential data; included with "Value of items that cannot be disclosed."

[1] Production as measured by mine shipments, sales, or marketable production (including consumption by producers).

[2] Includes a small quantity of anthracite mined in States other than Pennsylvania. In 1971, value excluded that of Arizona, which is withheld to avoid disclosing individual company confidential data; value included with "Nonmetal items that cannot be disclosed."

[3] Grindstones, pulpstones, grinding pebbles, sharpening stones, and tube mill liners.

[4] Excludes abrasive stone, bituminous limestone, bituminous sandstone, and soapstone, all included elsewhere in table.

Table 3.—Minerals produced in the United States and principal producing States in 1974

Mineral	Principal producing States, in order of quantity	Other producing States
Antimony ore and concentrate	Idaho, Mont., Nev.	
Aplite	Va.	
Asbestos	Calif., Vt., Ariz., N.C.	
Asphalt (native)	Tex., Utah, Ala., Mo.	
Barite	Nev., Mo., Ga., Ark	Alaska, Calif., Idaho, Ill., Tenn.
Bauxite	Ark., Ala., Ga.	
Beryllium concentrate	Utah.	
Boron minerals	Calif.	
Bromine	Ark., Mich., Calif.	
Calcium-magnesium chloride	Mich. and Calif.	
Carbon dioxide (natural)	N. Mex., Calif., Colo., Utah.	
Cement	Calif., Tex., Pa., Mich	Ala., Ariz., Ark., Colo., Fla., Ga., Hawaii, Idaho, Ill., Ind., Iowa, Kans., Ky., La., Maine, Md., Minn., Miss., Mo., Mont., Nebr., Nev., N. Mex., N.Y., N.C., Ohio, Okla., Oreg., S.C., S. Dak., Tenn., Utah, Va., Wash., W. Va., Wis., Wyo.
Clays	Ga., Tex., Ohio, N.C	All other States except Alaska, R.I., Vt.
Coal	Ky., W. Va., Pa., Ill	Ala., Alaska, Ariz., Ark., Colo., Ind., Iowa, Kans., Md., Mo., Mont., N. Mex., N. Dak., Ohio, Okla., Tenn., Tex., Utah, Va., Wash., Wyo.
Copper (mine)	Ariz., Utah, N. Mex., Mont	Alaska, Calif., Colo., Idaho, Ill., Maine, Mich., Mo., Nev., Okla., Oreg., Tenn., Wash., Wis.
Diatomite	Calif., Nev., Wash	Kans. and Oreg.
Emery	N.Y.	
Feldspar	N.C., Conn., Ga., Calif	Ariz., Colo., Okla., S. Dak., Wyo.
Fluorspar	Ill., Mont., Tex., Nev	Colo., Ky., N. Mex., Utah.
Garnet, abrasive	Idaho and N.Y.	
Gold (mine)	S. Dak., Nev., Utah, Ariz	Alaska, Calif., Colo., Idaho, Mont., N. Mex., Oreg., Tenn., Wash.
Graphite	Tex.	
Gypsum	Calif., Mich., Tex., Iowa	Ariz., Ark., Colo., Idaho, Ind., Kans., La., Mont., Nev., N. Mex., N.Y., Ohio, Okla., S. Dak., Utah, Va., Wash., Wyo.
Helium	Kans., Tex., Okla., Ariz.	
Iodine	Mich.	
Iron ore	Minn., Mich., Calif., Wyo	Ala., Ariz., Ark., Colo., Ga., Idaho, Mo., Mont., Nev., N. Mex., N.Y., N.C., Pa., S. Dak., Tex., Utah, Wis.
Kyanite	Va., Ga., Fla.	
Lead (mine)	Mo., Idaho, Colo., Utah	Ariz., Calif., Ill., Maine, Mont., Nev., N. Mex., N.Y., Okla., Oreg., Wash., Wis.
Lime	Ohio, Pa., Mo., Tex	Ala., Ariz., Ark., Calif., Colo., Conn., Fla., Hawaii, Idaho, Ill., Ind., Iowa, Kans., Ky., La., Md., Mass., Mich., Minn., Miss., Mont., Nebr., Nev., N. Mex., N.Y., N. Dak., Okla., Oreg., S. Dak., Tenn., Utah, Va., Wash., W. Va., Wis., Wyo.
Lithium minerals	N.C., Nev., Calif.	
Magnesite	Nev.	
Magnesium chloride	Tex.	
Magnesium compounds	Mich., Calif., N.J., Fla	Del., Miss., Tex., Utah.
Manganiferous ore	Minn. and N. Mex.	
Manganiferous residuum	N.J.	
Marl, greensand	N.J.	
Mercury	Calif., N.Y., Nev., Alaska.	
Mica, scrap	N.C., Ala., Ga., S.C	Ariz., Conn., N. Mex., S. Dak.
Molybdenum	Colo., Ariz., N. Mex., Utah	Calif. and Nev.
Natural gas	Tex., La., Okla., N. Mex	Ala., Alaska, Ariz., Ark., Calif., Colo., Fla., Ill., Ind., Kans., Ky., Md., Mich., Miss., Mo., Mont., Nebr., N.Y., N. Dak., Ohio, Pa., Tenn., Utah, Va., W. Va., Wyo.
Natural gas liquids	Tex., La., Okla., N. Mex	Ala., Alaska, Ark., Calif., Colo., Fla., Ill., Kans., Ky., Mich., Miss., Mont., Nebr., N. Dak., Pa., S. Dak., Utah, W. Va., Wyo.
Nickel	Oreg.	
Olivine	Wash. and N.C.	

Table 3.—Minerals produced in the United States and principal producing States in 1974—Continued

Mineral	Principal producing States, in order of quantity	Other producing States
Peat	Mich., Ill., Ind., Fla	Calif., Colo., Ga., Iowa, Maine, Md., Mass., Minn., Mont., N.J., N. Mex., N.Y., N. Dak., Ohio, Pa., S.C., Vt., Wash., Wis.
Perlite	N. Mex., Ariz., Calif., Nev	Colo. and Idaho.
Petroleum, crude	Tex., La., Calif., Okla	Ala., Alaska, Ariz., Ark., Colo., Fla., Ill., Ind., Kans., Ky., Mich., Miss., Mo., Mont., Nebr., Nev., N. Mex., N.Y., N. Dak., Ohio, Pa., S. Dak., Tenn., Utah, Va., W. Va., Wyo.
Phosphate rock	Fla., Idaho, Tenn., N.C	Mo., Mont., Utah, Wyo.
Platinum-group metals	Alaska.	
Potassium salts	N. Mex., Utah, Calif.	
Pumice	Oreg., Calif., Ariz., N. Mex	Colo., Hawaii, Idaho, Kans., Nev., Okla., Utah, Wash.
Pyrites ore and concentrate	Tenn., Colo., Ariz.	
Rare-earth metal concentrate	Calif., Ga., Fla.	
Salt	La., Tex., N.Y., Ohio	Ala., Calif., Colo., Kans., Mich., Nev., N. Mex., N. Dak., Okla., Utah, W. Va.
Sand and gravel	Alaska, Calif., Mich., Ill., Tex	All other States.
Silver (mine)	Idaho, Ariz., Mont., Utah	Alaska, Calif., Colo., Ill., Maine, Mich., Mo., Nev., N. Mex., N.Y., Okla., Oreg., S. Dak., Tenn., Wash., Wis.
Sodium carbonate (natural)	Wyo. and Calif.	
Sodium sulfate (natural)	Calif., Colo., Nev	
Staurolite	Fla.	
Stone	Pa., Ill., Tex., Fla	All other States except Del.
Sulfur (Frasch)	Tex. and La.	
Talc, soapstone, pyrophyllite	N.Y., Mont., Vt., Tex	Ala., Ark., Calif., Ga., Md., Nev., N.C., Oreg., Pa., Va., Wash.
Tin	Colo., N. Mex., Alaska.	
Titanium concentrate	N.Y., Fla., N.J., Ga.	
Tripoli	Ill., Okla., Ark., Pa.	
Tungsten concentrate	Calif., Colo., Nev	Ariz., Idaho, Mont., Utah, Wash.
Uranium	N. Mex., Wyo., Colo., Utah	Tex. and Wash.
Vanadium	Ark., Colo., Idaho, Utah	N. Mex.
Vermiculite	Mont. and S.C.	
Wollastonite	N.Y.	
Zinc (mine)	N.Y., Mo., Tenn., Colo	Ariz., Calif., Idaho, Ill., Maine, Mont., Nev., N.J., N. Mex., Okla., Oreg., Pa., Utah, Va., Wash., Wis.
Zircon concentrate	Fla. and Ga.	

Table 4.—Value of mineral production in the United States and principal minerals produced in 1974

State	Value (thousands)	Rank	Percentage of U.S. total	Principal minerals, in order of value
Alabama	$764,746	19	1.39	Coal, petroleum, cement, stone.
Alaska	448,437	23	.81	Petroleum, sand and gravel, natural gas, stone.
Arizona	1,562,234	9	2.83	Copper, molybdenum, sand and gravel, cement.
Arkansas	406,821	26	.74	Petroleum, bromine, stone, natural gas.
California	2,797,080	3	5.07	Petroleum, cement, sand and gravel, natural gas.
Colorado	750,299	20	1.36	Petroleum, perlite, coal, sand and gravel.
Connecticut	35,362	47	.06	Stone, sand and gravel, feldspar, lime.
Delaware	[1] 3,798	50	([2])	Sand and gravel, magnesium compounds, clays, gem stones.
Florida	1,043,895	14	1.89	Phosphate rock, petroleum, stone, cement.
Georgia	363,100	29	.66	Clays, stone, cement, sand and gravel.
Hawaii	42,042	44	.08	Stone, cement, sand and gravel, pumice.
Idaho	208,558	31	.38	Silver, phosphate rock, zinc, sand and gravel.
Illinois	1,149,210	11	2.08	Coal, petroleum, stone, sand and gravel.
Indiana	440,690	24	.80	Coal, cement, stone, petroleum.
Iowa	176,720	32	.32	Cement, stone, sand and gravel, gypsum.
Kansas	889,398	18	1.61	Petroleum, natural gas, natural gas liquids, cement.
Kentucky	2,563,210	4	4.65	Coal, stone, petroleum, natural gas.
Louisiana	8,146,578	2	14.77	Petroleum, natural gas, natural gas liquids, sulfur.
Maine	36,348	45	.07	Cement, sand and gravel, zinc, stone.
Maryland	172,880	33	.31	Coal, stone, cement, sand and gravel.
Massachusetts	62,109	43	.11	Stone, sand and gravel, lime, clays.
Michigan	1,040,067	15	1.89	Iron ore, petroleum, cement, copper.
Minnesota	1,026,366	16	1.86	Iron ore, sand and gravel, stone, cement.
Mississippi	391,155	28	.71	Petroleum, natural gas, sand and gravel, cement.
Missouri	691,049	21	1.25	Lead, cement, stone, zinc.
Montana	574,801	22	1.04	Petroleum, copper, coal, cement.
Nebraska	98,634	42	.18	Petroleum, cement, sand and gravel, stone.
Nevada	257,876	30	.47	Copper, gold, sand and gravel, diatomite.
New Hampshire	13,691	48	.02	Sand and gravel, stone, clays, gem stones.
New Jersey	140,748	37	.26	Stone, sand and gravel, zinc, magnesium compounds.
New Mexico	1,941,544	8	3.52	Petroleum, natural gas, copper, natural gas liquids.
New York	440,573	25	.80	Cement, stone, zinc, salt.
North Carolina	155,869	35	.28	Stone, sand and gravel, cement, feldspar.
North Dakota	159,427	34	.29	Petroleum, coal, natural gas liquids, sand and gravel.
Ohio	1,107,670	12	2.01	Coal, stone, lime, cement.
Oklahoma	2,123,690	7	3.85	Petroleum, natural gas, natural gas liquids, cement.
Oregon	103,920	40	.19	Stone, sand and gravel, cement, nickel.
Pennsylvania	2,374,512	6	4.30	Coal, cement, stone, lime.
Rhode Island	5,982	49	.01	Stone, sand and gravel, gem stones.
South Carolina	105,171	39	.19	Cement, stone, clays, sand and gravel.
South Dakota	102,627	41	.19	Gold, cement, stone, sand and gravel.
Tennessee	395,608	27	.71	Coal, stone, zinc, cement.
Texas	13,711,144	1	24.85	Petroleum, natural gas, natural gas liquids, cement.
Utah	952,045	17	1.72	Copper, petroleum, coal, gold.
Vermont	35,453	46	.06	Stone, asbestos, sand and gravel, talc.
Virginia	1,058,207	13	1.92	Coal, stone, cement, sand and gravel.
Washington	143,916	36	.26	Cement, sand and gravel, stone, coal.
West Virginia	2,403,177	5	4.36	Coal, natural gas, stone, cement.
Wisconsin	114,763	38	.21	Stone, sand and gravel, iron ore, cement.
Wyoming	1,437,200	10	2.60	Petroleum, sodium compounds, coal, uranium.
Total	55,172,000	--	100.0	

[1] Incomplete total.
[2] Less than ½ percent.

Platinum:				
Ore, concentrate, metal and alloys in ingots, bars, sheets, anodes, other forms, including scrap troy ounces	439,452	61,379	474,494	78,142
Palladium, rhodium, iridium, osmiridium, ruthenium, and osmium (metal and alloys including scrap) do	188,074	16,246	361,260	39,279
Platinum-group manufactures, except jewelry	NA	4,282	NA	3,753
Rare-earth metals, including cerium ore, metal, alloys, lighter flints pounds	109,766	286	192,144	503
Silicon:				
Ferrosilicon short tons	15,984	4,051	6,575	3,338
Silicon carbide, crude and in grains do	7,723	3,413	14,112	5,813
Silver:				
Ore, concentrates, waste, sweepings thousand troy ounces	3,007	7,322	12,699	53,956
Bullion, refined do	8,208	20,316	5,691	27,695
Tantalum:				
Ore, metal, other forms thousand pounds	360	3,962	704	6,813
Powder do	202	5,312	233	7,008
Tin:				
Ingots, pigs, bars, etc.:				
Exports long tons	2,540	12,099	5,908	47,774
Reexports do	866	3,236	2,507	15,700
Tin scrap and other tin-bearing material except tinplate scrap do	4,862	3,262	7,325	5,950
Titanium:				
Ore and concentrate short tons	1,494	353	3,264	727
Sponge (including iodide titanium and scrap) do	4,142	3,601	4,730	9,288
Intermediate mill shapes and mill products, n.e.c do	745	8,748	1,719	19,600
Dioxide and pigments do	20,769	14,021	30,540	24,696
Tungsten, ore and concentrates:				
Exports thousand pounds	90	239	1,187	4,835
Reexports do	--	--	88	292
Uranium:				
Ores and concentrates (U_3O_8 content) pounds	109,934	737	--	--
Metal do	14,737	270	20,496	322
Compounds do	4,028,095	26,107	4,682,926	30,855
Isotopes (stable) and their compounds	NA	17,041	NA	2,786
Radioactive materials thousand curies	15,615,135	12,303	25,431,262	16,571
Special nuclear materials	NA	223,516	NA	158,267
Vanadium: Ore and concentrate, pentoxide, etc. (vanadium content) pounds	464,399	1,157	406,235	1,327
Ferrovanadium do	2,832,762	8,734	2,670,321	7,863
Zinc:				
Slabs, pigs, or blocks short tons	14,566	8,259	19,062	16,511
Sheets, plates, strips, other forms n.e.c do	2,480	2,100	3,487	3,842
Waste, scrap, and dust (zinc content) do	7,032	2,717	12,088	6,280
Semifabricated forms, n.e.c do	15,077	10,565	28,456	27,343
Zirconium:				
Ore and concentrate pounds	57,842,328	2,288	42,973,250	3,323
Metals, alloys, other forms do	1,016,437	12,425	1,650,695	18,195

See footnotes at end of table.

Table 9.—U.S. exports of principal minerals and products [1]—Continued

Mineral	1973		1974	
	Quantity	Value (thousands)	Quantity	Value (thousands)
NONMETALS				
Abrasives:				
Dust and powder of precious or semiprecious stones, including diamond dust and powder ---------- thousand carats --	9,928	$25,071	14,005	$34,822
Crushing bort ---------- do ----	40	138	11	25
Industrial diamonds ---------- do ----	516	4,208	981	5,460
Diamond grinding wheels ---------- do ----	746	4,223	894	5,574
Other natural and artificial metallic abrasives and products ----------	NA	49,329	NA	69,627
Asbestos:				
Exports:				
Unmanufactured ---------- short tons --	65,900	9,251	55,114	8,643
Products ---------- do ----	NA	40,705	NA	60,256
Reexports:				
Unmanufactured ---------- do ----	542	91	6,609	549
Products ---------- do ----	NA	72	NA	140
Barite:				
Natural barium sulfate ---------- do ----	68,086	2,884	61,245	2,518
Lithopone ---------- do ----	986	357	1,185	967
Boron: Boric acid, and borates, crude and refined ---------- do ----	210,233	26,216	253,847	42,610
Cement ---------- do ----	324,740	8,980	289,844	14,860
Clays:				
Kaolin or china clay ---------- do ----	781,798	30,528	848,878	42,080
Fire clay ---------- do ----	196,337	3,820	224,110	5,988
Other clays ---------- do ----	1,168,495	45,426	1,376,888	66,148
Feldspar, leucite, nepheline, nepheline syenite ---------- thousand pounds --	19,107	466	36,688	662
Fluorspar ---------- short tons --	[r] 2,428	[r] 171	5,847	316
Gem stones:				
Diamonds ---------- thousand carats --	259	314,172	284	404,639
Pearls ----------	NA	473	NA	817
Other ----------	NA	21,770	NA	19,625
Graphite ---------- short tons --	7,958	992	12,189	1,698
Gypsum:				
Crude, crushed or calcined thousand short tons --	68	3,135	132	3,910
Manufactures, n.e.c ----------	NA	4,225	NA	6,934
Lithium hydroxide ---------- thousand pounds --	1,043	605	1,198	1,118
Kyanite and allied minerals ---------- short tons --	98,714	5,552	135,982	8,205
Lime ---------- do ----	36,914	1,208	31,639	1,516
Magnesium compounds:				
Magnesite, dead-burned thousand pounds --	101,520	6,104	102,533	7,749
Magnesite, crude, caustic calcined, lump, or ground ---------- do ----	18,608	4,196	21,465	5,088
Mica sheet, waste and scrap, and ground ---------- pounds --	14,588,464	2,201	16,842,858	3,085
Mica, manufactured ---------- do ----	1,155,852	3,064	1,053,980	3,430
Mineral-earth pigments, iron oxide, natural and manufactured ---------- short tons --	14,363	6,702	15,585	9,437
Nitrogen compounds (major) thousand short tons --	[r] 4,539	[r] 317,591	3,751	565,649
Phosphate rock ---------- do ----	13,932	113,295	14,174	256,697
Phosphatic fertilizers:				
Superphosphates ---------- do ----	967	70,990	1,179	222,711
Ammonium phosphates ---------- do ----	2,235	189,064	1,992	358,807
Elemental phosphorus ---------- do ----	26,679	12,256	33,653	20,075
Mixed chemical fertilizer ---------- do ----	375	34,084	474	58,476
Pigments and compounds (lead and zinc):				
Lead pigments ---------- short tons --	2,240	1,025	3,395	1,926
Zinc pigments ---------- do ----	[r] 8,062	[r] 2,440	13,430	7,405
Potash:				
Fertilizer ---------- do ----	1,578,716	57,997	1,414,598	66,175
Chemical ---------- do ----	39,229	10,660	38,290	14,712
Pumice and pumicite ---------- thousand pounds --	6,190	765	5,821	1,211
Quartz, natural, quartzite, cryolite, chiolite ---------- do ----	724	134	3,002	808
Salt:				
Crude and refined -- thousand short tons --	609	4,400	521	4,276
Shipments to noncontiguous territories ---------- do ----	[r] 20	[r] 1,820	19	1,798

See footnotes at end of table.

Table 9.—U.S. exports of principal minerals and products [1]—Continued

Mineral	1973 Quantity	1973 Value (thousands)	1974 Quantity	1974 Value (thousands)
NONMETALS—Continued				
Sand and gravel:				
Sand:				
Construction .... short tons	422,483	$793	658,801	$1,132
Industrial .... do	845,359	7,136	1,123,954	9,864
Gravel .... do	475,894	667	472,896	663
Sodium and sodium compounds:				
Sodium sulfate .... do	45	2,049	51	3,250
Sodium carbonate .... do	425	16,064	564	34,156
Stone:				
Dolomite, block .... do	59	652	86	1,559
Limestone, crushed, ground broken do	2,316	5,400	2,793	7,753
Marble and other building and monumental .... thousand cubic feet	NA	1,244	NA	1,920
Stone, crushed, ground, broken thousand short tons	765	4,819	625	4,850
Manufactures of stone	NA	948	NA	2,077
Sulfur:				
Crude .... thousand long tons	1,771	34,830	2,580	95,516
Crushed, ground, flowers .... do	r 5	1,461	21	1,829
Talc, crude and ground .... short tons	180,102	6,618	182,706	6,711
MINERAL FUELS				
Carbon black .... thousand pounds	192,665	24,056	201,737	32,947
Coal:				
Anthracite .... thousand short tons	717	11,240	735	16,577
Bituminous .... do	r 52,870	1,002,457	59,926	2,420,334
Briquets .... do	92	5,107	113	6,729
Coke .... do	1,395	33,138	1,278	43,564
Natural gas .... thousand cubic feet	84,805,211	43,152	107,873,053	68,676
Petroleum:				
Crude .... thousand barrels	697	2,620	1,072	13,565
Gasoline .... do	1,692	20,737	655	12,105
Jet fuel .... do	824	4,087	655	7,637
Naphtha .... do	1,561	19,671	1,293	27,211
Kerosine .... do	81	811	33	525
Distillate fuel oil .... do	2,526	25,680	307	5,518
Residual fuel oil .... do	8,388	23,578	4,261	41,232
Lubricating oil .... do	10,728	173,546	11,297	321,951
Asphalt .... do	338	3,262	341	5,238
Liquefied petroleum gases .... do	9,927	57,191	9,033	94,464
Wax .... do	942	24,176	862	34,464
Coke .... do	34,668	127,182	40,790	181,171
Petrochemical feedstocks .... do	6,815	32,500	5,558	65,712
Miscellaneous .... do	1,168	27,886	1,194	44,433
Total	XX	7,539,909	XX	12,733,090

Table 10.—U.S. imports for consumption of principal minerals and products[1]

Mineral	1973		1974	
	Quantity	Value (thousands)	Quantity	Value (thousands)
METALS				
Aluminum:				
Metal ---- short tons --	[r] 508,184	[r] $225,545	508,648	$312,479
Scrap ---- do ----	[r] 46,824	[r] 16,754	74,748	42,569
Plates, sheets, bars, etc ---- do ----	[r] 58,794	[r] 48,255	46,081	47,489
Aluminum oxide (alumina) ---- do ----	[r] 3,406,689	[r] 211,288	3,627,024	270,617
Antimony:				
Ore (antimony content) ---- do ----	16,679	10,903	14,655	20,866
Needle or liquated ---- do ----	51	73	86	271
Metal ---- do ----	692	745	2,203	7,550
Oxide ---- do ----	4,651	6,095	6,269	15,580
Arsenic:				
White (As_2O_3 content) ---- do ----	[r] 13,496	[r] 2,045	13,742	2,449
Metallic ---- do ----	648	2,630	707	3,651
Bauxite, crude ---- thousand long tons --	[r] [2] 12,778	NA	[2] 14,308	NA
Beryllium ore ---- short tons --	1,586	481	1,368	414
Bismuth ---- pounds --	[r] 2,683,671	[r] 9,688	1,898,744	15,606
Boron:				
Carbide ---- do ----	322,236	395	75,429	265
Boric acid ---- do ----	20,161	3	844,811	149
Calcium borate, crude ---- do ----	36,431,521	568	42,427,527	852
Cadmium:				
Metal ---- short tons --	[r] 1,948	[r] 12,963	1,985	14,674
Flue dust (cadmium content) ---- do ----	[r] 174	[r] 611	166	603
Calcium:				
Metal ---- pounds --	110,407	78	109,252	121
Chloride ---- short tons --	7,357	317	3,599	156
Chromate:				
Ore and concentrates (Cr_2O_3 content) thousand short tons --	412	21,028	481	28,532
Ferrochrome ---- do ----	[r] 105	[r] 37,198	102	55,261
Metal ---- do ----	3	6,080	2	5,388
Cobalt:				
Metal ---- thousand pounds --	[r] 18,398	[r] 53,772	14,791	49,661
Oxide (gross weight) ---- do ----	1,150	2,714	1,509	4,514
Salts and compounds (gross weight) do ----	62	51	2	12
Columbium ore ---- do ----	2,826	2,201	3,129	3,207
Copper (copper content):				
Ore and concentrates ---- short tons --	19,582	16,029	84,981	180,269
Regulus, black, coarse ---- do ----	139	106	2,426	12,033
Unrefined, black, blister ---- do ----	128,166	159,922	200,607	383,491
Refined in ingots, etc ---- do ----	[r] 207,739	[r] 264,967	313,349	551,442
Old and scrap ---- do ----	[r] 18,981	[r] 23,540	31,109	50,640
Ferroalloys, n.e.c ---- do ----	62,520	21,297	81,668	87,848
Gallium ---- kilograms --	11,124	6,073	6,536	4,107
Gold:				
Ore and base bullion ---- troy ounces --	[r] 234,694	19,388	329,357	45,974
Bullion ---- do ----	3,610,073	336,762	2,321,981	350,706
Indium ---- do ----	811,527	986	492,978	1,906
Iron ore ---- thousand long tons --	43,296	533,488	48,029	696,298
Iron and steel:				
Pig iron ---- short tons --	445,626	28,925	342,348	41,038
Iron and steel products (major):				
Iron products ---- do ----	38,048	19,118	49,524	29,328
Steel products ---- do ----	[r] 15,569,833	3,026,099	16,696,508	5,553,379
Scrap ---- do ----	336,693	18,716	188,480	26,166
Tinplate ---- do ----	11,940	384	12,645	861
Lead:				
Ore, flue dust, matte (lead content) do ----	[r] 94,299	[r] 17,882	62,691	15,180
Base bullion (lead content) ---- do ----	4	1	831	331
Pigs and bars (lead content) ---- do ----	[r] 178,116	[r] 52,937	118,367	57,693
Reclaimed scrap, etc. (lead content) do ----	[r] 3,116	[r] 588	1,286	334
Sheet, pipe and shot ---- do ----	[r] 772	[r] 308	196	138
Magnesium:				
Metallic and scrap ---- do ----	[r] 2,916	[r] 1,437	4,815	3,518
Alloys (magnesium content) ---- do ----	389	1,104	440	1,578
Sheets, tubing, ribbons, wire, other forms (magnesium content) ---- do ----	20	129	50	185
Manganese:				
Ore (35% or more manganese) -- do ----	722,685	37,403	592,818	45,091
Ferromanganese (manganese content) ---- do ----	[r] 303,885	[r] 53,337	327,874	88,426
Metal ---- do ----	2,452	1,100	2,506	1,379

See footnotes at end of table.

Table 10.—U.S. imports for consumption of principal minerals and products[1]—Continued

Mineral	1973 Quantity	1973 Value (thousands)	1974 Quantity	1974 Value (thousands)
METALS—Continued				
Mercury:				
Compounds ---- pounds --	3,543	$30	62,807	$153
Metal ---- 76-pound flasks --	46,026	12,151	52,180	13,948
Minor metals, selenium and salts --- pounds --	590,173	6,023	841,259	10,611
Molybdenum:				
Ore (metal content) ---- do ----	458,315	963	155,125	217
Waste and scrap ---- do ----	94,961	197	100,159	218
Metal ---- do ----	34,626	366	53,947	574
Compounds ---- do ----	2,270,433	2,083	1,456,055	1,515
Nickel:				
Pigs, ingots, shot, cathodes -- short tons --	120,083	343,494	137,314	450,342
Plates, bars, etc ---- do ----	1,628	7,708	1,310	7,446
Slurry ---- do ----	38,749	81,851	42,999	96,959
Scrap ---- do ----	2,642	3,906	3,699	8,545
Powder and flakes ---- do ----	7,291	23,067	9,371	33,545
Ferronickel ---- do ----	89,780	70,532	102,430	87,255
Oxide ---- do ----	6,301	13,466	6,449	15,081
Platinum-group metals:				
Unwrought:				
Grains and nuggets (platinum) troy ounces --	19,146	2,396	71,154	18,626
Sponge (platinum) ---- do ----	499,271	73,108	833,122	150,563
Sweepings, waste and scrap -- do ----	84,534	10,229	129,320	18,116
Iridium ---- do ----	19,701	4,816	28,980	9,482
Palladium ---- do ----	496,065	36,613	588,014	74,483
Rhodium ---- do ----	72,856	15,587	97,058	39,957
Ruthenium ---- do ----	67,218	3,375	63,884	3,678
Other platinum-group metals -- do ----	243,584	33,877	234,789	45,337
Semimanufactured:				
Platinum ---- do ----	155,715	22,949	199,355	35,388
Palladium ---- do ----	658,240	43,500	750,073	75,553
Rhodium ---- do ----	20,355	1,761	1,549	898
Other platinum-group metals -- do ----	3,806	621	7,821	1,335
Radium: Radioactive substitutes ----	NA	[r] 5,603	NA	7,565
Rare-earth metals, ferrocerium and other cerium alloys ---- pounds --	38,206	127	57,519	238
Silicon (silicon content):				
Metal ---- short tons --	8,302	11,955	5,914	16,700
Ferrosilicon ---- do ----	[r] 63,724	[r] 21,316	92,951	66,350
Silver (general imports):				
Ore and base bullion thousand troy ounces --	33,990	74,927	34,568	150,284
Bullion ---- do ----	[r] 81,373	[r] 215,897	89,963	432,868
Sweepings, waste, dore ---- do ----	15,472	39,832	8,864	40,642
Tantalum ore ---- thousand pounds --	1,097	2,858	1,897	7,169
Tin:				
Ore (tin content) ---- long tons --	[r] 4,798	[r] 18,511	5,877	35,999
Blocks, pigs, grains, etc ---- do ----	45,845	195,246	39,602	289,592
Dross, skimmings, scrap, residues and alloys, n.s.p.f ---- do ----	1,281	1,322	1,761	1,186
Tin foil, powder, flitters, etc ----	NA	6,956	NA	9,331
Titanium:				
Ilmenite[3] ---- short tons --	[r] [3] 306,939	[r] [3] 11,856	[3] 318,720	[3] 13,715
Rutile ---- do ----	[2] 208,808	[3] 27,158	[2] 235,507	[3] 37,445
Metal ---- pounds --	13,648,385	11,389	20,090,390	19,546
Ferrotitanium ---- do ----	512,547	178	4,592,316	3,122
Compounds and mixtures ---- do ----	121,789,426	28,057	70,866,757	25,216
Tungsten (tungsten content):				
Ore and concentrates -- thousand pounds --	[r] 10,884	[r] 23,725	11,096	40,696
Waste and scrap ---- do ----	102	309	179	711

---

[p] Preliminary. NA Not available.

W Withheld to avoid disclosing individual company confidential data.

[1] May not represent total world production because confidential U.S. data are excluded for some commodities. World totals include reported figures and reasonable estimates; however, for some commodities where data were not available, no reasonable estimates could be made and none have been included.

[2] Includes small quantities of lignite for People's Republic of China and Pakistan, and anthracite for Colombia.

[3] Includes low- and medium-temperature and gashouse coke.

[4] Less than ½ unit.

[5] Includes Puerto Rico.

[6] Kaolin sold or used by producers.

[7] Year ended June 30 of year stated (United Nations).

[8] World total exclusive of the U.S.S.R.

[9] Dry bauxite equivalent of crude ore.

[10] Recoverable.

[11] Includes byproduct ore.

[12] Includes secondary.

[13] Smelter output from domestic and foreign ores, exclusive of scrap.

[14] Lead refined from domestic and foreign ores; excludes lead refined from imported base bullion.

[15] Data from American Iron and Steel Institute. Excludes production of castings by companies that do not produce steel ingot.

[16] Includes tin content of alloys made directly from ore.

Abrasive Materials

By Robert G. Clarke [1]

The overall output of natural abrasives, excluding emery, decreased 14% in quantity and 5% in value compared with 1973. Tripoli-type crudes decreased in both quantity and value. Special silica stone products decreased slightly in quantity but showed an increase in value. The sales of garnet were the highest in its history for both quantity and value. Emery production was down 13% in quantity.

The overall production of artificial abrasives increased 13% in quantity and 61% in value. Silicon carbide production remained essentially unchanged in quantity, but the value increased. For all other artificial abrasives the increase in production was well over that of 1973 in both quantity and value.

---

[1] Physical scientist, Division of Nonmetallic Minerals.

Table 1.—Salient abrasive statistics in the United States

Kind	1970	1971	1972	1973	1974
Natural abrasives (domestic) sold or used by producers:					
Tripoli (crude) short tons	68,105	75,184	87,864	101,519	81,721
Value thousands	$520	$569	$797	$929	$516

Value thousands	$665	$568	$670	$677	$717
Garnet short tons	18,837	18,984	18,916	22,772	24,684
Value thousands	$1,936	$1,984	$1,957	$2,380	$2,551
Emery short tons	W	1,586	2,883	2,884	2,520
Value thousands	W	W	W	W	W
Artificial abrasives [2] short tons	561,107	472,299	584,680	[3] 645,813	[3] 730,018
Value thousands	$85,772	$79,027	$92,958	[3] $108,308	[3] $175,678
Foreign trade (natural and artificial abrasives):					
Exports (value) do	$64,338	$60,685	$64,219	$82,969	$115,508
Reexports (value) do	$28,085	$21,711	$26,746	$29,413	$29,793
Imports for consumption (value) do	$96,467	$89,085	$106,512	$136,655	$142,974

W Withheld to avoid disclosing individual company confidential data.

[1] Includes grinding pebbles, grindstones, oilstones, tube-mill liners, and whetstones.

[2] Production of silicon carbide and aluminum oxide (United States and Canada); shipments of metallic abrasives (United States).

[3] Includes production of aluminum zirconium oxide (United States and Canada.).

FOREIGN TRADE

Imports of abrasive materials were 5% more in value than in 1973, and exports plus reexports increased 29%. Net exports, the excess of exports, and reexports over imports, were $2.3 million, the first occurrence of net exports historically for abrasive materials. The volume, as well as the unit values, of most abrasive materials exported and reexported increased.

The major influence on the total value of trade continued to be industrial diamond. Industrial diamond imports totaled 18.4 million carats of loose material valued at $62.9 million, a decrease of 4% in both quantity and value from that of 1973. The exports of industrial diamond, loose, amounted to 15.0 million carats, an increase of 43%, and the value was $40.3 million, an increase of 37%. Reexports of similar industrial diamond amounted to 3.7 million carats, a decrease of 18%, and the value was $29.6 million, an increase of 1%. The diamond content in diamond wheels, exported and reexported, amounted to 901,000 carats, an increase of 20%, the declared value was $5.6 million, an increase of 33%. The imports of diamond wheels are listed by number and value; the value in 1974 decreased to $971,000 from $1,037,000 in 1973.

The 1974 receipts of industrial diamond from Ireland were 8.3 million carats, valued at $18.7 million, reflecting a decrease of 13% in quantity and 12% in value from those of 1973. The share of imports provided by Ireland was 45% of the total quantity and 30% of value. Of the industrial diamond listed as powder or dust, synthetic diamond was 4.6 million carats valued at $9.3 million, and natural diamond was 7.2 million carats valued at $15.2 million.

TRIPOLI

Although different in some respects, fine-grained, porous, silica materials are discussed as a group because they have similar properties and end uses. Commercially, the term "tripoli" is applied to material from Arkansas, Missouri, and Oklahoma; and the term "amorphous" or "soft" silica is applied to the material from the southern Illinois area. Rottenstone mined in Pennsylvania is more earthy, but its properties render it suitable for end uses similar to those of tripoli and amorphous silica. Production of crude tripoli (table 1) decreased 20% in quantity and 44% in value. Processed tripoli sold or used (table 5) decreased 4% in quantity but increased 6% in value. The uses for processed tripoli in 1974 were 59% for abrasives and 39% for fillers compared with 62% and 36%, respectively, in 1973.

Tripoli producers in 1973 were Malvern Minerals Company, Garland County, Ark., which produced crude and finished material, and The Carborundum Co., which produced crude in Ottawa County, Okla., and finished material in Newton County, Mo. Illinois Minerals Co. and Tammsco, Inc., both in Alexander County, Ill., produced amorphous silica. Keystone Filler and Manufacturing Co., in Lycoming County, Pa., mined and processed rottenstone. The major use of amorphous silica and rottenstone was for abrasive purposes; the minor use was as a filler.

Prices quoted in Engineering and Mining Journal, December 1974, for tripoli and amorphous silica were as follows:

Tripoli, paper bags, carload lots, f.o.b., in cents per pound:	
White, Elco, Ill.: Air floated through 200 mesh	1.4
Rose and cream, Seneca, Mo. and Rogers, Ark:	
Once ground	2.90
Double ground	2.90
Air float	3.15
Amorphous silica, bags, f.o.b., in dollars per ton:	
Elco, Ill.:	
Through 200 mesh, 90% to 95%	$28
Through 200 mesh, 96% to 99%	29
Through 325 mesh, 90% to 95%	30
Through 325 mesh, 96% to 98%	32.50
Through 325 mesh, 98% to 99.4%	34
Through 325 mesh, 99.5%	48.50
Through 400 mesh, 99.9%	71
Below 15 micrometers, 99%	78.50
Below 10 micrometers, 99%	100
Dierks, Ark.:	
200 mesh	30
325 mesh	40

SPECIAL SILICA STONE PRODUCTS

Special silica stone products include the following: Oilstones from Arkansas, whetstones from Arkansas and Indiana, grindstones from Ohio, grinding pebbles and deburring media from Minnesota and Wisconsin, and tube-mill liners from Minnesota. Although the output decreased about 10%, the value increased 6%.

Producers of oilstones and whetstones in Garland County, Ark., were John O. Glassford, Hiram A. Smith, Cleve Milroy, Arkansas Abrasives, Inc., and Norton Pike Division of Norton Co. In Lawrence County, Ind., Hindostan Whetstone Co. operated a plant to finish its stone obtained from a quarry in Orange County, Ind. Cleveland Quarries Co. produced grindstones at its Amherst quarry, Lorain County, Ohio. Jasper Stone Co. produced grinding pebbles and tube-mill liners from its quarry in Rock County, Minn., and Baraboo Quartzite Co., Inc., produced deburring media at its quarry in Sauk County, Wis.

Table 6.—Special silica-stone products sold or used in the United States[1]

Year	Quantity (short tons)	Value (thousands)

1971	2,849	563
1972	3,241	670
1973	3,466	677
1974	3,184	717

[1] Includes grinding pebbles, grindstones, oilstones, tube-mill liners, and whetstones.

NATURAL SILICATE ABRASIVES

Garnet.—Sales of domestic garnet were at an alltime high in 1974; the quantity sold increased 8% and the value increased 7% over the respective quantity and value in 1973. Crushing, grinding, and screening were the customary processing for standard sizes and grits used in coated abrasives and in loose abrasive applications. To meet specifications for some special end uses, additional sophisticated treatments were applied to the grain. There were three active producers—two in Idaho and one in New York. Barton Mines Corp., Warren County, N.Y., was the largest producer and sold its garnet for use in coated abrasives, glass grinding and polishing, and metal lapping. Emerald Creek Garnet Milling Co., and Idaho Garnet Abrasive Co. produced garnet from placer deposits in Benewah County, Idaho. The Idaho producers reported their garnet was used in sandblasting, water filtration, as a filler in rubber products, and for miscellaneous abrasive lapping applications.

Average of prices for New York garnet, f.o.b. North Creek, N.Y., 2,000-pound release, in 330- to 370-pound containers were as follows, in cents per pound:

Untreated for manufacturing of coated abrasives:	
Grades 16 through 36	18
Grades 40 through 220	20
Grades 240 through 280	23
Grades 320 through 600	25
Untreated for technical grinding and lapping:	
Mesh sizes 20 to 240	15
Mesh sizes 280 to 360	20
Micrometer sizes 27 to 23	22
Micrometer sizes 20 to 8	25
Micrometer sizes 6 to 5	19
Micrometer sizes 4 to 2	34

Prices for Idaho garnet, f.o.b. Seattle, ranged from 5.5 to 10 cents per pound.

Table 7.—Abrasive garnet sold or used by producers in the United States

Year	Quantity (short tons)	Value (thousands)
1970	18,837	$1,936
1971	18,934	1,934
1972	18,916	1,957
1973	22,772	2,380
1974	24,684	2,551

NATURAL ALUMINA ABRASIVES

Corundum.—Domestic production of abrasive-grade corundum on a commercial scale was last reported in 1918. The corundum used by domestic industry for many years was imported from Southern Rhodesia, but sanctions imposed in 1968 by the United Nations halted this trade. In 1969, the Office of Emergency Preparedness dropped corundum from the list of strategic and critical materials for stockpiling. Domestic industry imported corundum from the Republic of South Africa in 1973 and 1974 for local consumption.

Prices quoted in Engineering and Mining Journal, December 1974, for corundum, per short ton of crude, c.i.f. U.S. ports were as follows, in dollars:

Crystal	120–130
Boulder	70–75

Emery.—Two producers of emery were active in 1974; De Luca Emery Mine, Inc., and Bates Mine, both near Peekskill in Westchester County, N.Y. Data on value of production were withheld to avoid disclosing individual company confidential data. The quantity of emery produced decreased to 2,520 tons from the 2,884 tons produced in 1973. Domestic emery was used mostly in aggregate for heavy-duty nonslip floors, pavements, and stair treads. Smaller amounts of domestic emery were used in coated abrasives and tumbling abrasives.

World production data for emery are principally for Greece and Turkey. In 1973, production of emery in Greece was estimated to be 7,716 short tons. Production of emery in Turkey in 1973 was reported as 101,724 short tons valued at $923,000.

Prices quoted in Industrial Minerals, No. 87, December 1974, for emery, per metric ton, c.i.f. main European port were as follows, in dollars:

Coarse grain	90–105
Medium and fine grain	90–113

Table 8.—Natural corundum: World production by country

Total	8,458	8,605	8,658

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Southern Rhodesia presumably continued to produce natural corundum at a significant level (several thousand tons annually), and both Argentina and Kenya may have produced minor quantities of this commodity, but output is not reported, and available information is inadequate for formulation of reliable estimates of output levels.

INDUSTRIAL DIAMOND

Domestic production of synthetic industrial diamond in 1974 was estimated to be 19 million carats, an increase of 2 million carats over that of 1973. Secondary production, comprising salvage from used diamond tools and from wet and dry diamond-containing wastes, was estimated to be 2 million carats.

The Government stockpile inventory as of December 31, 1974, was 35.9 million carats of crushing bort and 21.1 million carats of stones. The objectives for both categories are zero, and the inventories were considered excess. Still available for disposal from prior enabling legislation were 12.2 million carats of bort and 1.1 million carats of stones. The inventory of small diamond dies was 25,473, of which the objective was 7,900, and 17,573 was excess.

Exports and reexports of industrial diamond dust and powder, which included synthetics, were 14.4 million carats valued at $35.8 million. Crushing bort, except dust and powder, exported amounted to 500,000 carats valued at $3.3 million. Exports and reexports of stones were 3.8 million carats valued at $30.7 million. The total of exports and reexports of dust and powder, bort, and stones was 18.7 million carats valued at $69.9 million.

Table 9.—U.S. imports for consumption of industrial diamond (excluding diamond dies)

WORLD REVIEW

Botswana.—In October, the Government announced its intent to take a 50% share in the equity of the Orapa diamond mine of De Beers Consolidated Mines, Ltd.[2] The arrangements were likely to result in an increase in the Government's share of the profits from Orapa from about 50% to more than 75%. De Beers introduced a third working shift in June, which raised the output from 2.4 million carats per year to 3 million carats.[3] The average recovery ratio of industrial to gem-quality stones recovered at Orapa is roughly 85:15.[4] The smaller Dk 1 pipe discovered by De Beers about 30 miles southeast of Orapa has been under an economic feasibility study for about 2 years. De Beers is negotiating with the Government on terms to bring the new mine into production.

Central African Republic.—Diamond production in 1974 was nearly 25% higher than that of 1973. Total exports of 343,950 carats valued at $14,372,000 accounted for about 35% of the nation's foreign exchange receipts. Société Centrafricaine d'Exploitation Diamantifére (SCED), a new company formed in 1973 by Cominco, Ltd., of Canada and Diamond Distributors Inc. of New York, had a successful first year and was planning to expand its river dredging operations.

Ghana.—Yearly production between 1968 and 1973 in Ghana's two diamondiferous areas—the Birim Basin (Eastern Region) and the Bonsa Region (Western Region) —has averaged 2.47 million carats, according to the Ghana Department of Mines.[5] Three companies, Ghana Consolidated Diamond, Ltd. (G.C.D.L.), Cayco (Ghana) Ltd., and the Amalgamated Diamond Corp., are actively engaged in mining diamonds in the Birim River Basin. First International Natura Corp. (FINCO) of the United States completed exploration in the Birim and Pra River Basins within an area of 24.7 miles from the confluence of the Birim and Pra Rivers. The Ghana Government will own 55% of the FINCO prospect. G.C.D.L., which is 55% owned by the Government of Ghana, and 45% by Consolidated African Selection Trust, produced about 96% of the diamond output in Ghana in the period 1968–73.

Greenland.—About a dozen small industrial diamonds were found at Fiskenaesset near the southern tip of Greenland according to the Aarhus Stifstidende, a Copenhagen newspaper.[6] De Beers Consolidated Mines Ltd., of the Republic of South Africa, planned further investigation to determine the source of the diamond.

Indonesia.—The state mining company, P. N. Aneka Tambang, closed its plant that processed alluvium for diamond at Talang Intan, Cempaka Putih, South Kalimantan following unfavorable results after a 5-year trial program. Mining for diamond in Indonesia is at a low level.

Ivory Coast.—Société Anonyme de Recherches et d'Exploitation Minières en Côte d'Ivoire and Waston Company experienced decreased diamond production due to a breaking-in period for new processing equipment at their respective plants.[7]

Lesotho.—On March 1, 1974, Finance Minister, E. R. Sekhonyana, announced that an agreement in principle had been reached between De Beers Diamond Corp. and the Government of Lesotho on opening the Letseng-la-terae diamond mine.[8] De Beers will improve the access road and carry out the mining operation. The project was estimated at over $30 million of which $4.5 million was for infrastructure and $25.5 million for capital work. About 2 years would be needed to reach production. The Government will have 25% equity and be represented on the Board of Directors. De Beers will handle the marketing of diamond through the Central Selling Organization by means of a diamond sales company registered in Lesotho.

Southern Rhodesia.—Kimberlitic Searches Ltd., a prospecting subsidiary of De Beers Consolidated Mines Ltd., was granted an exclusive prospecting order for about 60 square miles in the Bulawayo mining district effective until August 23, 1976.[9] This is the fourth exclusive prospecting order for De Beers, and to date, no indication of any commercial finds has been given. The granting of the order signifies that the application company wishes to conduct a more detailed examination.

South Africa, Republic of.—Diamond sales by the Central Selling Organization in 1974 were R849 million ($1,189 million U.S.), or 7.8% lower than in 1973.[10] Sales in the first half of 1974 set a new record, and the reduction in the total was caused by a marked deterioration in sales in the second half. During this period excess production was absorbed into stock. No breakdown was given for sales of either gem stones or industrial diamond. Notwithstanding the slowdown in the world economy, sales of industrial diamond were higher in 1974 in both volume and value. The widespread increase in exploration for new sources of energy and gold resulted in increased usage of stones in drill bits. Toward the end of 1974, the sorting and classifying of diamonds produced by De Beers in South and Southwest Africa was centralized in a new building at Kimberly, which is also the new headquarters of the Diamond Producers Association.

Zaire.—The Government announced a decision on November 30, 1973, to take possession of the Société Minière de Bakwanga (MIBA) by increasing its shareholdings from 50% to 100%.[11] MIBA has had an output of about 12 million carats of diamond in recent years. About 83% is bort, 15% is industrial stones, and 2% is gem quality.

TECHNOLOGY

Four articles speculated that the kimberlite formations in West Africa, prior to the separation of Africa and South America by the continental drift, were the possible origin of diamonds in the Guiana Shield.[12] The Mines Division of De Beers Diamond Research Centre in Johannesburg, Republic of South Africa, continued development work on a number of projects.[13] These included a jet attritioner mill and plant for re-treating fine tailings, the use of centrifuges for treating slimes, magnetic separation of fine gravity concentrates, and the use of a heavy-media cyclone.

The invention of an inexpensive, flexible diamond abrasive tool with low carat content received the Richardson Gold Medal Award for Outstanding Merit from the Institute of Patentees and Inventors, London.[14] Tools of the new design have been used successfully for grinding and polishing stone, leveling ceramic tiles and glass, and surfacing plastics and a variety of woods. The basis of the invention is a flexible, meshlike structure on which the industrial diamond is deposited only on the land, exposed by the intersection of the weft and warp. About 16% of the total surface area of the tool contains diamond.

An article reported the results of research on three strength testing methods for diamond.[15] Diamond specimens researched were invariably small, irregular, and unique in their impurities and defects. The first study, the Hertzian method of strength measurements in which an indenter is pushed against the solid under test and the load measured, revealed that diamond must be used as the indenter also to obtain reliable results. The second study, a compression test of single particles to fracture, showed that the results depended

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Total (gem plus industrial) diamond output for each country is actually reported except where indicated to be an estimate by footnote. In contrast, the detailed separate reporting of gem diamond and industrial diamond represents Bureau of Mines estimates in the case of every country except the Central African Republic (1972 and 1973), Lesotho (1972 and 1973), Liberia (all years), Guyana (1972 and 1973), and Venezuela (1972 and 1973), where sources give both total output and detail. The estimated distribution of total output between gem and industrial diamond is conjectural in the case of a number of countries, based on unofficial information of varying reliability.

[2] Exports of diamond originating in Lesotho; excludes stones imported for cutting and subsequently reexported.

[3] Exports.

[4] Revised from data in previous edition, which were for years ending August 31 of that stated, to normal calendar year basis.

[5] All company output from the Republic of South Africa except for that from the Premier mine; also excludes company output from the Territory of South West Africa and Botswana.

on the shape, size, defect content of the specimen, and the anvil material. The third study, a comparison of the strength of natural diamond versus synthetic diamond showed that natural diamond is stronger in applications involving high temperatures or in heat cycling.

Abstracts relative to properties of diamond hard materials, machines, and patents were published monthly in the Industrial Diamond Review. Each issue, January to December 1974, contained from 14 to 18 pages of abstracts and patent information.

ARTIFICIAL ABRASIVES

Five firms in the United States and in Canada produced crude fused aluminum oxide in 1974. Operators of plants in both countries were: The Carborundum Co., Norton Co., and General Abrasive Co. The Exolon Co., and Simonds Canada Abrasive Co., Ltd., operated plants in Canada. The production of white, high-purity material was 33,298 tons, and production of regular grade was 207,921 tons. Of the combined output of white and regular, 11% was used for nonabrasive applications, principally in the manufacture of refractories. The production was 95% of the rated capacity of the furnaces assigned to fused aluminum oxide.

Four firms, The Carborundum Co., Exolon Co., General Abrasive Co., and Norton Co., produced crude fused alumina zirconia abrasive in the United States and in Canada in 1974. All production was reportedly used for abrasive applications. The output was 55% of the capacity of the furnaces assigned to the production of fused alumina zirconia.

Six firms in the United States and Canada produced silicon carbide in 1974. The Carborundum Co. operated plants in both countries and Electro-Refractories & Abrasives Canada, Ltd., Exolon Co., Norton Co. and General Abrasive Co., operated in Canada. These five companies produced crude for abrasive, refractory, and other nonabrasive uses. Satellite Alloy Corp. operated in the United States and produced crude for nonabrasive applications. Production by the six firms was 86% of capacity and 38% was reportedly used for abrasive applications. Nonabrasive use was 62% of the output and was mostly for refractory and metallurgical applications.

In the Stockpile Report to the Congress by the General Services Administration the inventory of crude fused aluminum oxide in calendar 1974 was reduced by 45,369 tons to 267,062 tons as of December 31; the stock of aluminum oxide abrasive grain was unchanged at 50,905 tons; and the stock of silicon carbide crude was reduced by 77,588 tons to 118,865.

Metallic abrasives were produced in 1974 by 13 firms in the United States. Steel shot and grit comprised 72% of the total quantity sold or used; chilled iron shot and grit, 17%; annealed iron shot and grit, 10%; other metallic abrasives comprised the remainder. The amounts from Ohio were 31% of the total sold or used, the highest of the producing States. Michigan, Indiana, and Pennsylvania followed in quantity sold or used; their combined total represented 60% of the national total. The remainder was from plants in Alabama, New York, and Connecticut. Three companies reworked material: Copperweld Steel Co. of Glassport, Pa.; Industeel Corp. of Pittsburgh, Pa.; and Kohler Co. of Sheboygan, Wis.

Producers of metallic abrasives were as follows:

Company	*Plants*
Abbott Ball Co	Hartford, Conn.
Abrasive Materials, Inc	Hillsdale, Mich.
Abrasive Metals Co	Pittsburgh, Pa.
The Carborundum Co	Butler, Pa.
Cleveland Metal Abrasive Co.	Birmingham, Ala. Howell, Mich. Springville, N.Y. Cleveland, Ohio Toledo, Ohio
Durasteel Co	Pittsburgh, Pa.
Ervin Industries, Inc	Adrian, Mich.
Globe Steel Abrasive Co	Mansfield, Ohio
Metal Blast, Inc	Cleveland, Ohio
National Metal Abrasive Co	Do.
Pellets, Inc	Tonawanda, N.Y.
Steel Abrasives, Inc	Hamilton, Ohio
Wheelabrator-Frye, Inc	Mishawaka, Ind.

TECHNOLOGY

One of the objectives of the Grinding Wheel Institute (GWI) is the development of greater understanding of how the grinding process works. A GWI project was carried out at Carnegie-Mellon University to study the vertical spindle surface grinding process. The first part of a 4-part series to explain the principle was published.[16] Major advances in grinding techniques have resulted from the development of digital programing, automatic loading, and automatic monitoring of machine operations.[17] New grinding wheels and equipment will permit high-speed grinding up to 16,000 feet per minute versus the present high of 12,000 feet per minute.

[17] Mari, A. New Era of Growth Seen in High Speed Grinding, Machining. Am. Metal Market and Metalworking News, v. 81, No. 141, pp. 11–12.

The addition of less than 1% boron to silicon carbide permits fabrication of ceramic parts such as jet blades for turbines, and combustors and duct works by conventional forming and sintering methods.[18]

Norway is the largest silicon carbide producing country in Europe, with an annual output of about 60,000 tons per year from three producers.[19] The technology and current operating practices of the producers, A/S Arendal Smelteverk (a Carborundum Co. subsidiary) at Arendal, K/S Orkla Exolon A/S & Co. (an affiliate of Exolon Co.) with Orkla Industries A. S. and with Christiana Spigerverk A/S at Orkanger on Trondheimsfjord, and Norton A/S (a Norton Co. subsidiary) near Lillesand in southern Norway, were described.

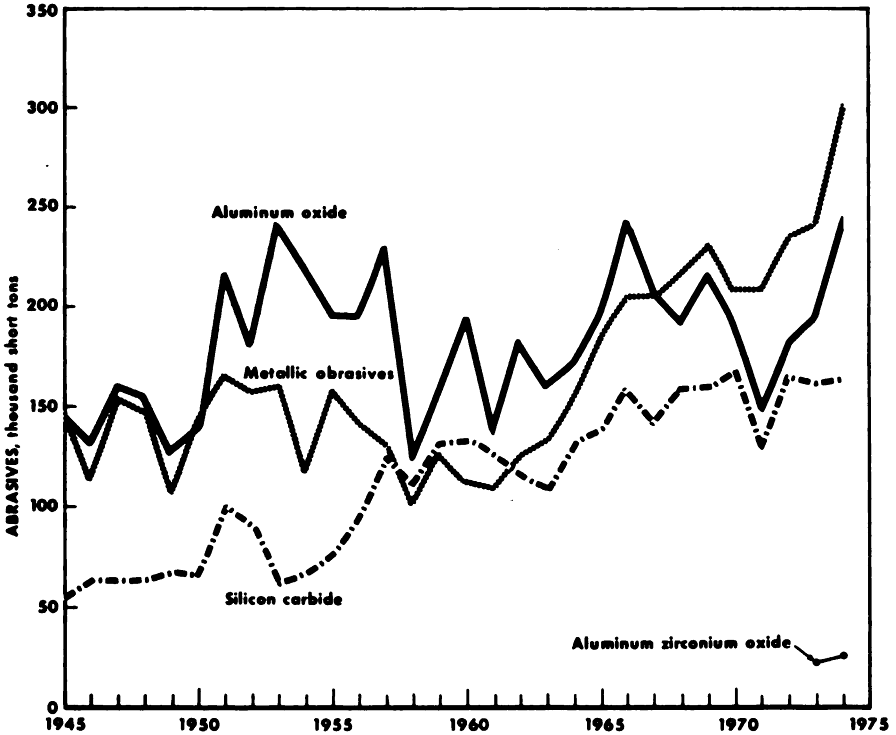

Figure 1.—Artificial abrasives production.

Aluminum

By John W. Stamper [1] and Christine M. Monroe [2]

Domestic production of primary aluminum of 4.9 million tons set a new record and was virtually 100% of yearend capacity. However, as economic activity began to decrease during the last half of the year aluminum demand also decreased; net shipments to domestic end users for the year were down almost 8%. By yearend, producers began to cut back production levels as inventories began to increase beyond normal levels.

The dramatic increase in energy costs following the oil embargo by the Organization of Petroleum Exporting Countries (OPEC) in late 1973 caused a significant increase in the cost of producing aluminum in 1974. The aluminum industry expanded its efforts to save energy throughout the aluminum production cycle.

The Aluminum Association, through a survey of its members, determined the quantity and form of energy used in 1972 and 1973 in the production of aluminum metal from the mining of bauxite through the production of aluminum mill products. The study showed that about 53% of the total energy used by the aluminum industry in 1973 was in the form of petroleum products and natural gas, 36% was coal, 10% was hydroelectric power, and 1% was nuclear energy. About 56% of the energy used was for generating either purchased or self-generated electricity at an energy efficiency of 31.5%.

r Revised.

Legislation and Government Programs.—The shipment of 510,741 tons of primary aluminum from government inventories during 1974 under the aluminum disposal program that became effective November 23, 1965, brought the total shipped under the program to almost 1.9 million tons. From December 1, 1965, to December 31, 1974, shipments of primary aluminum by the General Services Administration were as follows, in short tons:

1965	9,374	1970	24,261
1966	325,925	1971	21
1967	61,599	1972	6,125
1968	56,554	1973	730,249
1969	139,635	1974	510,741
		Total	1,864,484

All of the approximately 13,000 tons of aluminum metal (all grades) remaining in government inventories at the end of 1974 was sold or committed for sale but not delivered.

[2] Statistical assistant, Division of Nonferrous Metals.

DOMESTIC PRODUCTION

Primary.—Primary aluminum production capacity was unchanged in 1974; however, output increased 8% to a new record. Demand decreased toward the end of the year, and production at the Reynolds Metals Co. reduction plants at Jones Mills, Ark., and Listerhill, Ala., and at the Ormet Corp., Hannibal, Ohio, plant was reduced in December. Further reductions in the operating rates of these and other companies were scheduled for early 1975.

Aluminum Co. of America (Alcoa) planned to add about 60,000 tons per year to the capacity of its Badin, N.C., alumina reduction plant, raising annual capacity to about 180,000 tons in 1976. The company also was phasing out three 20,000-ton-per-year lines at its Massena, N.Y., reduction plant and replacing them with a 120,000-ton-per-year super line for a net increase of 60,000 tons, raising capacity there to about 190,000 tons per year. A $10.4 million loan was arranged with Bankers Trust Co. to finance installation of pollution control equipment for the new line and for carbon baking facilities. Alcoa also was planning to begin construction in 1977 to more than double its power-generating facilities at Rockdale, Tex., to 935 megawatts. The new generating plant was scheduled to use lignite.

Anaconda Aluminum Co. and Alcoa agreed to exchange information on the technology for producing alumina from materials other than bauxite, the present source of aluminum.

On January 30, 1974, Amax Inc. sold a 50% interest in substantially all of its aluminum business to Mitsui & Co., Ltd., a primary aluminum producer in Japan, for about $135 million in cash. The joint aluminum business will be operated by a separate corporation named Alumax Inc. Alumax owned 50% of the Intalco Aluminum Corp. 260,000-ton-per-year alumina reduction plant at Ferndale, Wash., and was constructing a 90,000-ton-per-year addition to the Eastalco Aluminum Co. aluminum plant at Frederick, Md., owned by Péchiney Ugine Kuhlmann (PUK) of France and Howmet Corp., which owned half of the Intalco plant. The new line, which was expected to be completed in 1975, cost $110 million and would be operated as a unit with the existing line. In addition, Alumax and Mitsui & Co., Ltd., were planning to build a 187,300-ton-per-year primary aluminum plant in Oregon if necessary government approval could be obtained. This plant was to be financed equally by Alumax and Mitsui & Co., Ltd., at a total estimated cost of $340 million.

Noranda Aluminum Inc. planned to double its capacity to produce primary aluminum at New Madrid, Mo., to 140,000 tons per year by 1976 at an estimated cost of $80 million. An additional $12 million was expected to be spent on improved pollution controls at the plant, which was built for Noranda in 1971 by Kaiser Aluminum & Chemical Corp. Kaiser also provides alumina to the plant under a long-term contract.

Noranda Mines Ltd. of Toronto, Canada, purchased the 38.5% interest owned by Olin Corp. in Frialco, a bauxite-alumina consortium in the Republic of Guinea. Noranda Aluminum, Inc., is a wholly-owned subsidiary of Noranda Mines.

Preliminary plans to triple the annual

capacity of the Revere Copper & Brass, Inc., primary aluminum plant at Scottsboro, Ala., with financial and technical assistance of six Japanese aluminum firms, were announced.

Consolidated Aluminum Inc. (Conalco) acquired 32% of the half interest formerly owned by Revere Copper & Brass, Inc. in the Ormet primary aluminum plant at Hannibal, Ohio. The purchase brought the interest in Ormet owned by Conalco to 66%.

Secondary.—Recovery of secondary aluminum from purchased aluminum-base scrap, calculated from reports to the Bureau of Mines, was 993,431 tons, 4% less than the quantity recovered in 1973. Calculated recovery of all metallic constituents from aluminum-base scrap in 1974 declined 4% to 1,058,091 tons.

The Bureau estimated that full coverage of the industry would indicate a total scrap consumption of 1,448,000 tons in 1974. On this basis, aluminum recovery would total 1,190,000 tons, and total metallic recovery would be 1,282,000 tons.

Based on data supplied by its members. The Aluminum Association estimated that 2.3 billion all-aluminum cans were returned in 1974 up from 1.6 billion cans estimated in 1973. Assuming that 23 to 25 cans make a pound, this quantity would be equivalent to about 79,000 tons of aluminum cans that were recycled in 1974. Reynolds Metals Co., a primary producer, estimated that it accounted for about 70% of the total cans collected in 1973 and announced that it was expanding its capability to collect aluminum cans throughout the United States. The $3 million program will bring the company's total to 83 collection centers and over 100 mobile units and will expand its recycling activities to 45 States.

Table 4.—Aluminum recovered from scrap processed in the United States, by kind of scrap and form of recovery

(Short tons)

Kind of scrap	1973	1974	Form of recovery	1973	1974
New scrap:			As metal	121,020	99,587

[1] Gross weight, including copper, silicon, and other alloying elements. Secondary smelters used 34,797 and 39,301 tons of primary aluminum in 1973 and 1974, respectively, in producing secondary aluminum-base alloys.

[2] No allowance was made for consumption or receipts by producing plants.

[3] Includes aluminum extrusion billet made from purchased aluminum-base scrap.

Several reports were published on can recycling activity by primary aluminum producers and others[3] and an assessment of the potential for recovering energy, aluminum, and other values from municipal wastes.[4]

Plans were announced for a $100 million industrial complex to be based on the Connecticut Resource Recovery Authority (CRRA) resources recovery plant to be located in Wallingford, Conn. City officials met with representatives of the glass recycling, detinning, steel, and aluminum industries to discuss locating ancillary reuse industries next to the separation center. It is estimated that the resource recovery center could turn out 26 tons of aluminum, 400 tons of glass, 380 tons of iron and steel, 11 tons of nonferrous metals other than aluminum, 300 tons of sand, and 300 tons of heavy organic matter each day. The organics would constitute feed for a proposed pyrolytic plant.

The Tennessee Valley Authority (TVA) was studying a plan for recycling solid wastes, including aluminum, from an area stretching across several States, and it has asked 31 equipment manufacturing companies to submit information on their ability to supply one or more 1,000-ton-per-day waste processing plants.

Success of the project depended on the results of tests to be conducted at the Shawnee Steam Plant near Paducah, Ky., to determine if the combustible portion of the refuse can be satisfactorily mixed with coal and burned in TVA's present plants and to determine if cost estimates are accurate.

CONSUMPTION

Domestic aluminum consumption as measured by net shipments to the domestic industry in 1974 was rising at a rapid rate at the beginning of the year, but the trend was reversed by yearend. Average end-use for 1974 was 7.8% below that of 1973. Applications in building and construction showed the greatest decrease, 15.2% below those in the previous year. Uses in transportation, consumer durables, and miscellaneous applications also decreased substantially, but shipments to the containers and packaging and machinery industries gained about 10% each. Electrical applications dropped moderately.

According to Aluminum Association data, aluminum shipments for the manufacture of windows, doors, and screens, which accounted for about 26% of the building and construction applications, totaled about 400,000 tons, 20% less than in 1973. Mobile homes accounted for about 139,000 tons, representing a 39% decline from 1973 shipments. Residential siding, the second largest use for building and construction, dropped only 7% to 266,000 tons; bridge, street, and highway construction actually increased slightly to about 89,000 tons.

In transportation, 1974 aluminum usage in passenger cars dropped 23% to 510,000 tons, while aluminum used in trucks and buses decreased only 10% to 187,000 tons. Trailers and semitrailers accounted for about 200,000 tons of aluminum in 1974, a 12% drop.

Air conditioners, freezers, and refrigeration applications accounted for about 151,000 tons of aluminum in 1974, a decline of 19%. Aluminum shipped for metal cans totaled 770,000 tons, up almost 18% from the 1973 level. In the machinery and equipment field, cryogenic, petroleum, and gas applications showed significant growth.

STOCKS

Reflecting the low level of demand, industry stocks of primary aluminum ingot at reduction plants increased from 62,234 tons at the beginning of the year to 145,757 tons at yearend. Although all producers do not report stocks of aluminum at reduction plants to the Bureau of Mines, the Bureau of Domestic Commerce (BDC) reported that the total metal inventory held by the aluminum industry, which includes stocks of all metal forms at reduction and other processing plants, also increased. Total industry stocks of aluminum metal, including scrap, rose from 2,183,031 tons at the beginning of the year to 2,577,768 tons at yearend.

PRICES

The primary aluminum price was under price controls at 29 cents per pound from January through March 29, 1974. Under an agreement between industry and the Cost of Living Council, the price of aluminum was decontrolled in stages through August when decontrol was completed. The price for primary aluminum was increased in successive stages to 31.5 cents per pound on March 29, 1974, to 33.5 cents per pound on June 3, to 36 cents on August 1, to 39 cents per pound on September 5, and remained at that level through the remainder of 1974.

Prices quoted by smelters for secondary aluminum alloys increased from a range of 34 to 40 cents per pound at the beginning of the year to a maximum range of 52 to 61.5 cents per pound at the end of July, and then declined to a range of 47 to 58 cents per pound at yearend.

The price range quoted for new scrap at the beginning of the year of 18.5 to 24 cents per pound rose to a maximum range of 28.5 to 35 cents per pound in April then decreased to a range of 17 to 18 cents per pound at yearend. Quotes for old scrap followed a similar pattern increasing from a range of 17 to 18 cents per pound in January to 28 to 30 cents per pound in April then declining to 11.5 to 14 cents per pound at yearend.

FOREIGN TRADE

Exports of crude and semicrude aluminum metal, including scrap, was 6.6% less than in 1973, reflecting weak world demand. Most of the decrease was accounted for by declines in exports of aluminum ingot and scrap, which were partially offset by increased exports of semimanufactured forms. As in past years, Canada was the principal recipient of U.S. aluminum exports mostly in the form of plates, sheets, and bars. Japan received most of the aluminum ingot.

U.S. imports for consumption of crude and semicrude aluminum increased slightly, and as in past years, Canada was the principal source, accounting for 80% of the crude metal and alloys and 65% of the scrap. Most of the remaining crude aluminum metal and alloys came from Ghana, and most of the remaining scrap came from the United Kingdom.

Table 12.—U.S. exports of aluminum, by class

Class	1973		1974	
	Quantity (short tons)	Value (thousands)	Quantity (short tons)	Value (thousands)

WORLD REVIEW

Estimated world demand for primary aluminum rose slightly over the 1973 level. However, by yearend demand declined sharply, and primary producers in Japan, Canada, and Australia cut production levels and postponed expansion plans in order to maintain reasonable inventory levels.

Expansion plans continued in many of the less developed areas of the world where the cost of power was expected to be low. Ghana, Guinea, and Trinidad announced tentative plans for new smelters. Planning for new plants continued in Papua New Guinea, Indonesia, and India.

e Estimate. p Preliminary. r Revised.

[1] Output of primary unalloyed ingot unless otherwise specified.

[2] Includes secondary.

[3] Includes alloys.

[4] Includes super-purity aluminum as follows in short tons: 1972—6,313; 1973—6,526; 1974—6,206.

[5] Turkey was credited with an estimated production of 10,000 tons of aluminum in 1973 in the previous edition of this chapter; information now available suggests that output, if any in 1973, was less than 10,000 tons; production (if any) in 1974 is as yet unreported and no reliable basis is available for estimating output level.

Argentina.—The Alumínio Argentino S.A. (ALUAR) smelter in Puerto Madryn came onstream in July. The Futaleufu hydroelectric project was not completed, and production of aluminum during 1974 was only 3,300 tons. Expansion of output to 110,000 tons per year was scheduled by mid-1975 with the addition of two gas-fired turbogenerators. The completion of the Futaleufu River hydroelectric complex in 1977 will permit production at planned capacity of 165,000 tons per year.

Australia.—Comalco Industries Pty. Ltd. delayed a 22,000-ton-per-year expansion at its Bell Bay, Tasmania, smelter. The new capacity was rescheduled to come onstream in 1976 instead of October 1975 as previously planned. Decreased demand forced Comalco to cut production at the 105,000-ton-per-year smelter by 9.5%.

Brazil.—Aluminio Brasileiro (Albras) announced plans to construct an aluminum complex in Belém. Included in the plans were an 88,000-ton-per-year smelter and an alumina refinery. Plans to develop the hydroelectric power potential of the Tocantins River continued. The smelter reportedly could be expanded to 704,000 tons per year by 1985.

Other expansions planned in Brazil included an increase to 31,000 tons per year at the Aluminium Co. of Canada, Ltd. (Alcan), smelter at Aratü by the second half of 1975 and possibly doubling of capacity to 62,000 tons per year by 1977. Cia. Brasileira de Alumínio announced plans to expand its Sorocaba plant to 77,000 tons per year by 1976 and to 121,000 tons per year by 1979.

Canada.—On July 8, 1974, Nippon Light Metal Co., Ltd. (NLM), and Alcan Aluminum Ltd. announced the formation of Alpac. The companies plan to produce 100,000 tons per year of primary aluminum at Alcan's Kitimat, British Columbia, smelter starting in 1977. Part of the alumina for the project will be supplied by NLM through a 100,000-ton-per-year contract with Comalco Industries Pty. Ltd., and the remainder will be supplied by Alcan's Jamaican and Australian refineries. The aluminum production will be split equally by the two partners. Due to the formation of Alpac, Alcan announced the expansion of the Kitimat smelter by 25,000 tons per year to 325,000 tons per year. The expansion was scheduled to come onstream in early 1976.

Lack of demand for primary aluminum at the end of 1974 forced Alcan to cut production by 100,000 tons per year or 10% of its Canadian capacity at the end of 1974.

Canadian Reynolds Metals Co. Ltd., reportedly was considering a 150,000-ton-per-year expansion at its Baie Comeau, Quebec, smelter. Capacity of the plant is currently 175,000 tons per year. Reynolds also was considering building a smelter in Newfoundland because of the relatively low cost of power. A hydroelectric plant at Churchill Falls, Labrador, and another under construction at Gull Island would supply power. Total power availability from the facilities was estimated at 6,825 megawatts. The government of Newfoundland reportedly insisted that fabricating facilities also be built in order to employ a larger portion of the population.

Egypt.—The Egyptian smelter at Nag Hamadi reportedly came onstream in 1974 with an initial capacity of 110,000 tons per year, to be expanded to 187,000 tons per year in 1975. Additional power may be required since the Nile has an uneven water level throughout the year. The U.S.S.R reportedly loaned Egypt $15 million toward the planned expansion and will take 75% of the aluminum production.

Germany, West.—Reynolds International, Inc. 110,000-ton-per-year smelter in Hamburg operated at a 27,000- to 33,000-ton-per-year level in 1974 as the result of a court order stemming from charges that the smelter did not meet fluoride emission standards. In 1975, the jurisdictional court was scheduled to take up the question of whether full-capacity operations would meet the antipollution standards.

Ghana.—A 50,000-ton-per year expansion was reportedly underway at the Volta Aluminium Co., Ltd. (VALCO) smelter in Tema. The expansion plans include raw materials storage facilities and improvements to the four existing potlines. Kaiser Engineers, Inc., was chosen to design and construct the expanded facilities, which should be completed by spring 1976. The cost of the improvements was estimated at $65 million. VALCO is owned by Kaiser Aluminum & Chemical Corp. (90%) and Reynolds Metals Co. (10%).

Kaiser and Ardeco, a consortium of five Japanese steelmakers, were reportedly undertaking a feasibility study for a 660,000-ton-per-year alumina refinery and a 110,000-ton-per-year smelter. Bauxite for the project would be supplied by Ghana.

Guinea.—The Governments of Guinea and Romania signed a preliminary agreement for a smelter to be built in Guinea by the two countries and for a hydroelectric project to be built by Romania.

Guyana.—The Governments of Guyana, Trinidad and Tobago, and Jamaica announced plans to build a smelter in Guyana. Construction was scheduled to start in January 1978 with completion of a 200,000-ton-per-year smelter expected in 1981. The Essequibo County hydroelectric plant was to supply the power. Guyana had 52% interest in the project with the remaining interests held by Jamaica (24%) and Trinidad and Tobago (24%).

India.—Power shortages resulting from severe droughts cut production at the Hindustan Aluminium Corp. Ltd. (Hindalco) smelter at Renukoot and the Madras Aluminium Co. Ltd. plant at Mettur. The Madras smelter reached capacity production of 28,000 tons per year at the end of 1974. Hindalco's plant was held at less than the 105,000-ton-per-year capacity level by the energy shortage and slowdowns resulting from labor differences.

The first stage of the Bharat Aluminium Co. Ltd. smelter at Korba, Madhya Pradesh, was scheduled to come onstream in 1975 with a 28,000-ton-per-year capacity level. Expansions were scheduled to continue until the plant achieved 110,000-ton-per-year capacity.

Plans for a new smelter in the Kohlapur district of Marashtra were announced by the Association of Aluminium Industries.

Indonesia.—Construction of the Asahan smelter in North Sumatra was scheduled to start in 1975. The initial capacity of 247,000 tons per year was to be expanded to 396,000 tons per year later. Cost of the smelter was estimated at $350 million, which was to be financed primarily by the Japanese Government. Power was to be supplied by a planned 500-megawatt hydroelectric plant on the Asahan River.

Iran.—The Iranian Aluminium Co. (IRALCO) announced tentative plans to increase the Arak smelter capacity from 50,000 tons per year to 120,000 tons per year by 1978. The cost was estimated at $50 million. Alumina for the plant was supplied by India.

Japan.—Oversupply due to lack of demand resulted in Japanese producers delaying several expansion startups. Nippon Light Metal Co., Ltd., deferred startup of a 44,000-ton-per-year potline at Niigata until September 1975. The expansion that was completed in 1974 raised the capacity of the smelter to 159,000 tons per year.

Mitsubishi Chemical Industries, Ltd.,

postponed indefinitely the startup of a 50,000-ton-per-year potline at Sakaide. Startup had originally been scheduled for March 1975. Other deferred expansion startups included the Sumitomo Chemical Co. Ltd., smelter at Toyo and the Mitsui Aluminium Industry Co. plant at Miike. Showa Denko K.K. postponed for 1 year the addition of a 50,000-ton-per-year potline at its Chiba smelter. The expansion, which will raise the capacity of the smelter to 210,000 tons per year of aluminum, was scheduled to come onstream in the fall of 1976.

The expansion by 87,000 tons per year to 175,000 tons per year of aluminum at the Mitsui Aluminium Industry Co. Omuta smelter was on schedule, with about half the new capacity due onstream in early 1975 and the remaining half 1 year later.

The start of construction of the Sumikei Aluminum Co. projected 180,000-ton-per-year aluminum smelter at Sakata in Yamagata was deferred until spring 1975. Furukawa Aluminium Co. Ltd. expected to satisfy pollution control requirements by the end of 1974 and to start construction in 1975 on the Mikuni aluminum smelter in Fukuni.

Sumitomo Chemical Co. Ltd., cut production by 10% at Toyama, Isoura, and Nagoya smelters in order to reduce inventories.

Korea, Republic of.—Tsvetmetpromexport of the U.S.S.R. and Ilosolbi of South Korea reportedly signed a contract for delivery of equipment and construction of a 25,000-ton-per-year aluminum smelter in Pukchang.

Mexico.—Plans were being formulated for a 120,000-ton-per-year aluminum smelter in Mexico. Alumina for the $90 million plant was to be supplied by Jamaica. Tentative partners in the smelter reportedly included the Mexican Government (51%), the Jamaican Government (29%), and Kaiser Aluminum & Chemical Corp. (20%).

Norway.—The Norwegian Government acquired Alcan Aluminium's 50% share in A/S Årdal og Sunndal Verk for $62 million on January 1, 1975. Under the agreement, Alcan will continue to supply the plant with alumina as well as to receive ingot.

Norsk Hydro A/S Karmøy Fabrikker announced tentative plans to build a second primary aluminum plant on Karmøy Island. Plans call for an initial capacity of 50,000 tons per year to be expanded to 80,000 tons per year over an extended period. The existing smelter has a capacity of 132,000 tons per year.

Det Norske Nitridaktieselskap (DNN) encountered problems with the Norwegian Government over pollution controls on the tentative expansion of the Tysseldal facility. The Government reportedly would prefer that a new, more competitive plant be built. DNN was also said to have encountered problems of financing the 20,000-ton-per-year expansion.

Papua New Guinea.—The Governments of Papua New Guinea and Australia and several Japanese companies reportedly undertook a feasibility study for a large aluminum smelter to be constructed in Niugini. The three groups also announced the consolidation of plans for a $1.5 billion hydroelectric project on the Purari River at Wabo.

Philippines.—Reynolds Metals Co. and the Philippine Government reportedly signed a letter of intent to build an aluminum smelter. Reynolds was to provide technical assistance in the design and construction of the facility. The proposed 110,000-ton-per-year plant, which was to be built near Ormoc, would use geothermal power.

Spain.—Alumina Espanola announced a change in location of its proposed alumina/aluminum complex because of possible pollution problems. The site was changed to San Cipriano in Jove-Cerro of Lugo Province. Construction was scheduled to start in 1975 with the plant due onstream in 1978. The company is owned by the State-owned Instituto Nacional de Industria (55%) and Alugasa Pechiney (45%).

Aluminio de Galicia, S.A. increased the production capacity of its La Coruña smelter by 14,000 tons per year to 75,000 tons per year. Further expansion was planned.

Sweden.—Gränges Aluminium AB announced plans to expand the capacity of its Sundsvall smelter by 52,000 tons per year to 147,000 tons per year. The furnaces will use a new process designed to lower energy requirements and to reduce pollution problems. Cost of the expansion was estimated at $75 million.

Taiwan.—Taiwan Aluminium Corp. announced plans to expand the current 42,-

000-ton-per-year capacity of its Kaohsiung smelter to 77,000 tons per year by the end of 1975. Additional planned expansions include 20,000 tons per year by 1978 and further expansion to 350,000 tons per year by 1983. Cost of the 1975 expansion was estimated at $52.6 million.

Trinidad.—The consortium composed of Trinidad and Tobago (34%), Guyana (33%), and Jamaica (33%) announced plans for a 200,000-ton-per-year smelter at Point Lisas, Trinidad. Trinidad was to supply natural gas as fuel and Yugoslavia would finance the project. Construction on the $350 million smelter was scheduled to start in January 1976 with startup planned for late 1977. Guyana and Jamaica would supply alumina.

U.S.S.R.—The Péchiney Ugine Kuhlmann Group confirmed a preliminary contract with the U.S.S.R. agreeing to build an alumina/aluminum complex at Sainsk. The 500,000-ton-per-year smelter will include semifabricating facilities, aluminum fluoride facilities, and a carbon anode plant. A 1-million-ton-per-year alumina refinery to be built on the Black Sea coast, 6,000 miles from the Sainsk smelter, was planned. Total cost of the project was estimated at $1 billion.

The Bratsk smelter was scheduled to be expanded to 385,000 tons per year in 1975. Additional facilities at the Krasnoyarsk smelter, which receives its power from the Angara Power Dam, were reported completed during 1974.

Venezuela.—Construction of the New Venalum smelter in Puerto Ordaz, Matanzas, began. Startup was scheduled for July 1977 with an initial capacity of 77,000 tons per year to be expanded later to 308,000 tons per year. The plant will be operated by Alumínio del Caroni, S.A. (Alcasa), owned 50% by Reynolds Metals Co. and 50% by Corporación Venezolana de Guyana (CVG), a government corporation. New Venalum is owned by CVG (80%), Showa Denko K.K. (7%), Kobe Steel (4%), Sumitomo Chemical (4%), Mitsubishi Kasei and Mitsubishi Metal (4%), and Marubeni (1%). The Japanese firms were scheduled to receive 176,000 tons per year of the expanded output.

Yugoslavia.—The 88,000-ton-per-year primary aluminum smelter at Mostar came onstream in 1974 with full production expected in 1975. Alumina was eventually to be supplied by the Bacevici refinery. The Péchiney Ugine Kuhlmann Group provided technical assistance on the project.

The first stage of the Boris Kidric smelter operated at 75,000 tons per year during 1974. A power shortage idled 56 cells during part of the year.

Zaire.—Reynolds Metals Co. announced a feasibility study for a primary smelter based on power from the Inga Dam. Alumina for the plant will be produced from local bauxite. Kobe Steel and Nippon Light Metals have reportedly expressed interest in the project.

TECHNOLOGY

The 1973 oil embargo and subsequent rise in energy costs inspired increased research and development to produce aluminum with better energy efficiency. In June 1974, a conference of industry and government representatives was held at Cambridge, Mass., to exchange information on energy use patterns in aluminum production and recycling processes and to recommend ways of improving energy efficiency of the processes. The conference was sponsored jointly by The Aluminum Association, the Center for Materials Science and Engineering of the Massachusetts Institute of Technology, and the Bureau of Mines. An overview of the results of the conference was published.[6]

Emphasis at the conference was placed on the energy required for producing alumina using the Bayer process, for reducing the alumina to metal by the Hall-Heroult process, and for melting and recycling operations.

Based on thermodynamics calculations, the theoretical energy requirement in the Bayer processes was given as 610,000 British thermal units (Btu) per short ton of alumina produced from bauxite. However, due to the losses of waste heat, practical energy requirements reportedly ranged from about 10 million to 22 million Btu per ton of alumina. Areas for significant potential improvement of the Bayer process included: (1) Reducing heat losses in existing equipment, (2) increasing the product yield, (3) using regenerative heating wherever possible, (4) reducing heat discharged with red mud, and (5) using fluid-bed calcination in place of rotary kiln.

---

[6] Aluminium. Conference on Energy Conservation and Recycling in the Aluminum Industry, Cambridge 1974. February 1975, pp. 178–182.

Average electrical requirements of the Hall-Heroult reduction step to produce a short ton of aluminum from alumina was given as 8 kilowatt-hours per pound, equivalent to about 55 million to 176 million Btu per ton, depending on whether the electric energy used was from hydrogenerating or from thermal-generating plants.

Significant reduction of the energy required in the Hall-Heroult reduction process was believed to be possible through basic research on the chemistry of the electrolyte, the electrolysis mechanism, and heat and fluid flow in the cell as influenced by thermal, gravitational, and electromagnetic forces in the cell. Development of permanent (nonconsumable) anodes and wettable cathode materials also were believed to be promising areas for research.

Although the industry average requirement of electricity in the conventional Hall-Heroult cell in 1974 was about 8 kilowatt-hours per pound of aluminum, a new plant using Hall-Heroult cells designed by Alcoa and operated by Anaconda was mentioned that utilized only 6.6 to 6.85 kilowatt-hours per pound. Péchiney was said to have operated an experimental Hall-Heroult type cell at 5.7 to 5.85 kilowatt-hours per pound. These latter figures show an efficiency comparable with the energy efficiency expected to be achieved at a new 15,000-ton-per-year plant based on electrolysis of aluminum chloride being built at Palestine, Tex., by Alcoa, which was expected to use 30% less energy in the reduction step than the Hall-Heroult cells.

Major energy savings could be achieved by avoiding as much remelting of metal as possible by using the hot metal, directly from the reduction cells, in continuous rod or sheet mills or in casting operations. About 1 million Btu per ton is theoretically required to melt aluminum compared with the present industry practice of about 4 to 12 million Btu per ton depending on furnace efficiency and the form of aluminum metal melted. Fuel consumption and thermal efficiencies of various remelt furnaces were given as follows:

	Fuel consumption, (Btu/lb)	Thermal efficiency, (percent)
Conventional furnaces-melt controlled	2,000–3,000	17–40
Charging box furnaces-2 chamber melt with salt cover	3,000–6,000	10–23
Rotary furnaces with molten salt	3,300–4,500	12–16
Induction furnaces, 60-cycle, 1,200 to 1,500 kilowatts:		
Hydroelectric source	860– 935	53–67
Thermal source	2,580–2,805	18–19

The summary report on the conference indicated that heat and material losses from remelting operations could be reduced by: (1) Consistent use of better methods to recover metal from dross and skimmings, (2) reduction of metal oxidation, (3) reduction of the quantity of in-house scrap that is generated, (4) recycling heat from casting operations, (5) avoiding large temperature gradients by mixing the molten metal, and (6) using oxygen enrichment.

The Aluminum Association provided the Bureau of Mines with results of a comprehensive study it conducted on energy use patterns of the domestic aluminum industry in 1972 and 1973. Based on data provided by its members, the Association aggregated the total use of fuels and electric energy by the aluminum industry to produce bauxite, alumina, and primary aluminum metal in the United States. Estimates of the fuels used by others to generate electricity that was purchased by the aluminum industry also were included. The energy used in producing aluminum ingot and mill shapes also was covered in the study, but that used by the secondary aluminum industry and aluminum foundries was for the most part excluded.

As shown in table 18 the energy data were aggregated by the type of energy used in five functional categories of the aluminum production cycle: (1) Bauxite (mining); (2) alumina (production); (3) hot metal production; (4) holding, casting, and melting; and (5) fabrication. Factors used by the Association to convert the different types of fuels and energy to a common energy unit, the Btu, are given in table 19.

Table 18.—Energy consumption by the aluminum metal industry in the United States[1]
(Billion Btu)

Energy used to mine metallurgical-grade bauxite and to produce alumina for subsequent reduction to metal is included under the bauxite and alumina categories, respectively. However, energy used to mine and produce special grades of bauxite and alumina for refractory, abrasive, and chemical uses is excluded. Energy used by the aluminum industry to produce lime and caustic is included under the alumina category if such materials were used to make alumina for aluminum metal production.

The hot metal production category includes electricity used in electrolytic cells to reduce the alumina to metal and the energy content of the coal, oil, gas, lignite, and nuclear fuels used to generate part of the electricity used by the industry, whether purchased or self-generated. In addition, the energy content of fuels used to make carbon anodes and cathodes as well as the energy content of carbon materials in the electrodes themselves, is included. Energy used by the aluminum industry to calcine green petroleum coke or to produce fluorides or cryolite used in producing metallic aluminum, also is included in the hot metal category. Energy used by others to produce purchased items (except electricity) is not included.

The holding, casting, and melting category includes energy used for holding furnace, ingot casting, and melting operations in the United States, whether located at the smelter or at fabricating plants. This category includes all operations immediately prior to any continuous casting operations such as for sheet and rod. Remelt operations are included. However, energy used for soaking, annealing, or heat treatment of mill products was included in the fabrication category.

The fabrication category includes energy used for the production of aluminum mill shapes beyond the ingot casting stage. Mill products include sheet, plate, and foil; extrusions, drawn tube, and welded tube; rod, bar, wire, and electrical conductor wire and cable; forgings and impacts; and powder and paste. Fuel used for intracompany shipping of products, if such fuel was purchased by members of the aluminum industry for use in company-owned carriers, and for some other miscellaneous fabricating uses also is included.

The energy content of purchased materials, such as carbon electrodes, alloying ingredients, packaging materials, plastics, adhesives, paints or coatings, plastic wire and cable coverings or insulation, and fuels consumed by a service business for the aluminum industry, such as noncompany common carriers, is not included.

Data in table 20 show fuel and hydropower use patterns for the industry's electrical power needs in 1972 and 1973. Of the 83.6 billion kilowatt-hours of electricity used by the aluminum industry in 1973, 36.6% was from hydroelectric facilities, and the remainder was thermally generated at an average efficiency from all fuel sources of 31.5%.

According to The Aluminum Association, Inc. total energy use per unit declined in 1973 relative to that in 1972. Inasmuch as both total industry production and total energy use in 1973 was greater than that in 1972, an expression of the improved energy efficiency in 1973 was derived by the Association by calculating the total energy that would have been used in 1973 if the use per unit in 1973 had been the same as that in 1972. This calculation indicated an overall energy savings by the aluminum industry in 1973 of 14.5 trillion Btu. This quantity of energy is equivalent to that contained in about 2.5 million barrels of oil.

Table 20.—Sources of electric energy used by the aluminum industry in the United States

Energy source	1972			1973		
	Electricity used [1] (billion kilowatt hours)	Thermal equivalent of electricity used [2] (billion Btu)	Total fuel used to generate electricity used [3] (billion Btu)	Electricity used [1] (billion kilowatt hours)	Thermal equivalent of electricity used [2] (billion Btu)	Total fuel used to generate electricity used [3] (billion Btu)
Hydropower	29.3	99,849	--	30.6	104,426	--
Coal	29.0	99,059	313,434	34.4	117,301	367,849
Natural gas	15.6	53,349	175,272	16.1	54,970	179,689
Oil	1.3	4,410	13,304	1.5	5,048	15,828
Nuclear	.7	2,413	7,427	1.0	3,471	10,681
Total	75.9	259,080	509,437	83.6	285,216	578,547

[1] Includes both self-generated and purchased electricity used by the aluminum industry.

[2] Thermal equivalent of 1 kilowatt-hour is equal to 3,413 Btu.

[3] Includes the thermal equivalent of thermally-generated electricity. Data include fuel used by aluminum companies for self-generation as well as estimated fuel usage by utilities to generate the electricity purchased by the aluminum industry. Self-generation fuel usage is based on reported efficiencies; purchased electricity fuel usage is measured at 10,500 Btu per kilowatt-hour and based on reported patterns of fuel usage by utilities from whom the electricity was purchased.

Source: The Aluminum Association, Inc.

Results of an intensive investigation of air pollution control methods available to the aluminum industry and the impact on the industry of the cost of controlling air emission of gases and solids from primary aluminum production facilities, within proposed standards, were published.[6]

Eight commercial metal producers joined the Bureau of Mines as cosponsors of research on extracting aluminum from domestic materials, to reduce dependence on imports. Using experimental miniplant facilities at the Bureau's Boulder City Metallurgy Research Laboratory in Nevada, several methods for producing alumina from plentiful domestic sources will be investigated. Most of the alumina from which aluminum metal is produced in the United States is presently made from imported bauxite. The aluminum companies cooperating with the Bureau on the miniplant project are Alcoa; Aluminium Co. of Canada, Ltd.; Amax Aluminum Co., Inc., Anaconda Aluminum Co.; Consolidated Aluminum Corp.; Kaiser Aluminum & Chemical Corp.; Martin Marietta Aluminum, Inc.; and Reynolds Aluminum Co. Each corporation is paying $50,000 per year over the next 3 years, and the Bureau is paying $400,000 per year. Costs for setting up the miniplant and for its first year of operation were paid entirely by the Bureau.

---

[6] Environmental Protection Agency. Background Information for Standards of Performance: Primary Aluminum Industry Volume 1: Proposed Standards. Office of Air and Waste Management, October 1974, 99 pp.

The miniplant is designed to convert roughly 70 pounds of an aluminum-bearing clay to 25 pounds of alumina per hour, using a nitric acid leaching process. Hydrochloric acid leaching of clay will be tested next. The facility runs around the clock, so that particular processing techniques having commercial promise can be evaluated and adjustments can be made, as needed, for improved efficiency.

When the experiments on clay are complete, new miniplant facilities being installed at Boulder City, Nev., will process anorthosite, alunite, and dawsonite in future stages of the program. Each of these aluminum-bearing minerals is plentiful in the United States.

Antimony

By Charlie Wyche [1]

Antimony was in short supply during the early months of 1974, although the recent upward trend in domestic mine production was maintained. The high demand for antimony, particularly antimony trioxide, resulted in major price increases and some slowdown in usage by consuming industries. The alltime high metal price turned previously uneconomical deposits into viable ore bodies that are currently being developed. The New York price of domestic antimony metal, RMM brand, rose from $0.94 per pound in January to $2.25 in June. The $2.25 per pound remained in effect through yearend. A 12% decline in consumption was undoubtedly related to the high price of antimony materials.

Domestic mine production rose for the second successive year, but primary smelter production declined moderately below the 1973 figure. Imports were up, continuing the fluctuating pattern that began in 1968.

Legislation and Government Programs.—At yearend Government stocks of antimony totaled 40,734 tons, of which 18,705 tons was in the national stockpile and 22,029 tons was in the supplemental stockpile. The stockpile objective for antimony has been reduced to zero, therefore the total inventory was excess.

The depletion allowance was 22% for domestic production and 14% for domestic companies engaged in foreign mining. There was no import tariff on antimony ore, and duty during 1974 was 0.1 cent per pound on crude antimony metal and 1.0 cent per pound on unwrought refined metal.

DOMESTIC PRODUCTION

MINE PRODUCTION

Domestic production of antimony in 1974 increased 21% to 661 tons, despite a reduction in domestic consumption. As in recent years, most of the metal (445 tons) was recovered as a byproduct from processing silver-lead-copper ore by the Sunshine Mining Co., Coeur d'Alene district, Idaho. Sunshine's output was 38% above that of 1973, reflecting a steady return to normal operation following several years of below average production. Byproduct antimonial lead recovered at primary lead smelters from domestic lead ores totaled 658 tons, significantly below the 1973 level. This material contained 8.8% antimony and was consumed as antimonial lead.

The U.S. Antimony Corp. located at Thompson Falls, Mont., completed expansion of its facilities during 1974, and both production and the number of antimony products are expected to increase. The company rebuilt its ore crushing facilities and moved into a new building. A 300-ton-per-day-capacity ball mill and additional flotation cells were added. A large furnace and a dust control system were installed in the antimony refinery. Currently, the company produces a 93%- to 95%-grade metal, but is upgrading the process to produce a 99.5%-grade metal and also antimony trioxide. Production in 1974, however, declined from the 1973 level. The decline was attributed to interruptions caused by the expansion program. Most of U.S. Antimony's mine output came from its Babbit mine.

Table 2.—Antimony mine production and shipments in the United States
(Short tons)

Year	Antimony concentrate (quantity)	Antimony	
		Produced	Shipped
1970	6,681	1,130	1,029
1971	4,721	1,025	1,073
1972	2,072	489	547
1973	2,468	545	494
1974	3,217	661	593

Four mines in Nevada produced and shipped antimony concentrates containing 47 tons of antimony. Most of the concentrates were processed to metal at the Intermountain Smelting Corp. in Salt Lake City, Utah.

SMELTER PRODUCTION

Primary.—Primary smelter output decreased 3% in relation to that of 1973, with oxide, sulfide, and byproduct antimonial lead registering losses. However, smelter production of metal and residues increased 6% and 12%, respectively. The source of feed materials for the smelters was as follows: 91% from foreign antimony ores and base metal ores, and 9% from domestic mine production of antimony concentrate and as a byproduct at domestic lead smelters. Byproduct antimony recovered at lead refineries represented 8% of the total primary antimony output. Virtually all of the byproduct antimony was consumed at the refineries in manufacturing antimonial lead. A small quantity was used to prepare oxide or processed to residues. Smelter production of primary products, in ratios approximating those of 1973, were as follows: Metal, 18%; oxide, 63%; sulfide and residues, 13%; and byproduct antimonial lead, 6%.

The NL Industries, Inc. smelter in Texas, Sunshine Mining Co. in Idaho, U.S. Antimony Corp. in Montana, and Intermountain Smelting Corp. in Utah produced antimony metal. Oxide was produced by American Smelting and Refining Company (ASARCO) Inc., Harshaw Chemical Co., M & T Chemicals Inc., and U.S. Antimony Corp. The Bunker Hill Co., ASARCO, and St. Joe Minerals Corp. produced byproduct antimonial lead. Antimony sulfide was produced by McGean Chemical Co. Inc., and M & T Chemicals Inc.

Table 3.—Primary antimony produced in the United States
(Short tons, antimony content)

Year	Class of material produced					Total
	Metal	Oxide	Sulfide	Residues	Byproduct antimonial lead	
1970	3,732	8,261	23	384	981	13,381
1971	3,816	6,272	18	136	1,132	11,374
1972	3,837	8,343	232	201	731	13,344
1973	2,859	11,273	92	1,839	1,143	17,206
1974	3,030	10,445	54	2,066	1,062	16,657

Table 4.—Byproduct antimonial lead produced at primary lead refineries in the United States
(Short tons)

Year	Gross weight	Antimony content				
		From domestic ores [1]	From foreign ores [2]	From scrap	Total	
					Quantity	Percent
1970	20,438	598	383	203	1,184	5.8
1971	19,686	828	304	59	1,191	6.0
1972	15,051	516	215	319	1,050	7.0
1973	15,455	731	412	24	1,167	7.6
1974	12,518	658	404	35	1,097	8.8

[1] Includes primary residues and a quantity of antimony ore.
[2] Includes foreign base bullion and small quantities of foreign antimony ore.

Secondary.—Antimonial lead recovered from scrap in 1974 totaled 23,570 tons, about 500 tons less than in 1973. Secondary smelters recovered 20,561 tons, primary smelters recovered 35 tons, and manufacturers and foundries recovered the remaining 2,974 tons. Old scrap, predominantly battery plates, generated about 87% of the secondary output; new scrap, mostly in the form of drosses and residues from various sources, supplied the remaining 13%. The scrap processed was essentially all from domestic sources. A percentage breakdown of old scrap by source was as follows: Batteries, 65%; type metal, 15%; babbitt, 11%; all other material, 9%. Drosses made up 9% of the new scrap, and residues supplied 5%. Approximately 2,000 tons of primary antimony was used to supplement secondary metal to meet commercial requirements; this was about 275 tons less than in 1973.

Table 5.—Secondary antimony produced in the United States, by kind of scrap and form of recovery
(Short tons, antimony content)

Kind of scrap	1973	1974
New scrap:		
Lead-base	3,527	2,950
Tin-base	62	43
Total	3,589	2,993
Old scrap:		
Lead-base	20,459	20,561
Tin-base	14	16
Total	20,473	20,577
Grand total	24,062	23,570

Form of recovery	1973	1974
In antimonial lead [1]	19,212	18,963
In other lead alloys	4,842	4,597
In tin-base alloys	8	10
Total	24,062	23,570
Value (millions)	$33.0	$85.7

[1] Includes 24 tons of antimony recovered in antimonial lead from secondary sources at primary plants in 1973 and 35 tons in 1974.

CONSUMPTION AND USES

Reflecting a tight supply and high prices, total consumption of antimony decreased 8% from the 1973 level of 44,675 tons to 41,041 tons. Antimony from primary sources accounted for 44% of the total (18,041 tons), and secondary metal contributed 56% (23,000 tons). Antimony oxide represented 53% of the raw material used, and antimony metal the remaining 47%. As shown in table 7, the nonmetals products section was separated into two parts to reflect more clearly the use of primary antimony in flame retardants. Secondary antimony, recovered chiefly from battery scrap, was used in the manufacture of antimonial lead and other hard-lead alloys.

Consumption of primary antimony in metal products decreased 12% in relation to 1973. In the largest use category, antimonial lead, requirements for antimony were down 10%. Consumption in bearings, sheet and pipes, castings, and type metal was also well below the 1973 level. Other uses such as cable covering, collapsible tubes, and solder showed small gains.

The consumption of antimony trioxide fell 15%. The 51% rise in oxide used in flame retardants failed to offset a 38% drop in other nonmetal products. In the nonmetal products section, antimony trioxide consumption was down in all subsections except one. Uses in ceramics and glass, pigments, and plastics showed the largest decline, reflecting a slowdown in the building industry. Higher demand for flame retardants resulted from stricter fire codes and a shift toward clothing made from materials that require flameproofing. The use of antimony trioxide in flame retardant is growing rapidly every year, and demand will continue to be high.

Of some 1,300 tons of antimony classified under "Other" nonmetal products, about 71% was used as sodium antimonate. This compound is used as an opacifier in enamel frits to add hardness and increase acid resistance. About 18% was consumed as chemicals, antimony sulfide, and antimony chloride (penta- and trichloride); the remaining 11% was used in other industrial applications.

Table 6.—Industrial consumption of primary antimony in the United States by class of material consumed

STOCKS

Industrial stocks of antimony totaled 11,694 tons at yearend, a 16% increase over the record level for 1973. Oxide increased, but metal stocks declined. The overall increase was due to large unused Government stocks purchased by industry in 1973.

PRICES

The U.S. dependence on antimony imports and the high worldwide demand for the metal resulted in a continuing upward trend in domestic prices. The four price increases that occurred in 1974 advanced RMM brand antimony metal from $0.94 to $2.25 per pound, New York, by mid-June. The record $2.25-per-pound price level remained in effect through yearend. The Lone Star grade increased to a record high of $2.67 during the same period. At the beginning of 1974, quotations for 60% European lump ores were $22.50 to $24.50 per short ton unit; yearend quotations were $31.30 to $32.20. The refusal of the People's Republic of China to make any significant quantities of antimony available at its Canton Fairs was a prime factor in the high prices. The quoted price range per pound of antimony oxide in late December was $1.84 to $2.16, up from $1.24 at the beginning of the year.

Table 9.—Antimony price ranges in 1974

Type of antimony	Price per pound
Domestic metal[1]	$0.92–$2.28
Foreign metal[2]	.90– 3.50
Antimony trioxide[3]	.87– 2.16

[1] RMM brand, f.o.b., Laredo, Tex.
[2] Duty-paid delivery, New York.
[3] Quoted in Metals Week.

FOREIGN TRADE

Exports of antimony material in 1974 totaled 1,464 tons, of which 593 tons was oxide and 871 tons was metal alloys, scrap, and waste. The 1974 combined value of $2,681,509 was more than 5 times the 1973 total. The large increase in value was due primarily to inflated prices for materials rather than an actual increase in the volume of exports. More than 35 countries, led by the Netherlands, Canada, the United Kingdom, Spain, and the Republic of Korea, accounted for around 97% of the metal, scrap, waste, and alloys exported. Oxide exports totaled 593 tons, 53% above those of 1973. The value of oxide totaled $1,049,980, and consignments were made to 18 countries. Canada was the leading recipient with 170 tons, followed by West Germany with 99 tons, and 74 tons went to the United Kingdom. The remaining 250 tons was distributed among 15 other countries.

General imports of antimony in various forms increased 4% to 22,119 tons. Imports of ore and concentrates declined to the lowest quantity since 1971, largely because of a combined drop of 34% from Bolivia, Turkey, and the Republic of South Africa. Increased receipts from Guatemala, Thailand, and the United Kingdom failed to offset the decrease from the major sources. With the processing of some of the Republic of South Africa ore to oxide, and Bolivia ore to metal, imports of ore from these countries can be expected to continue to decline. Because of oxide and metal production by these countries, imports of oxide increased from 4,600 to 6,300 tons (gross weight) and metal imports from 700 to 2,300 tons. Yugoslavia, the People's Republic of China, Mexico, and Japan were the principal sources for metal imports (76%). The United Kingdom and France supplied 57% of the oxide.

In addition to imports of ore, metal, and oxide, 565 tons of alloys containing antimony was imported. Belgium-Luxembourg and Thailand supplied 55% and 15% of this material, respectively. The Netherlands, Czechoslovakia, and Italy furnished most of the remainder. Total value of this material was $1.7 million.

WORLD REVIEW

World mine production of antimony in 1974 increased marginally to 77,700 tons from 76,700 tons in 1973. However, output in both the Republic of South Africa and Bolivia declined. The demand was high in most consuming countries, and many small producers increased production, offsetting the drop recorded by the major producers. The overall increase was due to the worldwide mine development and expansion plan that began in 1972.

Australia.—The Australian Antimony Corp. N.L. mine at Dorrigo, on the north coast of New South Wales, produced about 400 tons of antimony ore per day. The company purchased Broken Hill Antimony, Pty. Ltd., whose plant at Attanga, near Dorrigo, was used to process the ore. Reserves were estimated at 535, 000 tons. The company had a pilot plant in operation at Taylor's Arms, also near Dorrigo.

New England Antimony, Pty. Ltd., operated an antimony mine and mill at Hillgrove, near Armidale, in the New England district of New South Wales. Silver Valley Ltd. also developed a stibnite orebody at Hillgrove. The nearby Tulloch treatment plant was reconditioned to treat the ore.

Le Grand Minerals Ltd. investigated an antimony prospect at Mount Misery, in North Queensland. Reserves were estimated at 164,000 tons averaging 1% antimony. Metromar Minerals Ltd. and Australian Anglo-American Ltd. started the second phase of their exploration and evaluation program at the Blue Spec Gold prospect in the Pilbara region of Western Australia. Drilling results indicate ore reserves of 240,000 tons averaging 6% antimony. Initial plans call for a 200-ton-per-day mine and mill. The project, when completed, will cost $1.5 to $3 million.

Bolivia.—Work was reportedly proceeding as scheduled on construction of the antimony smelter begun by Skoda Export of Czechoslovakia in 1973. Production was scheduled to begin in 1975 at the 5,000-ton-per-year plant, which will also produce 1,000 tons per year of antimony trioxide.

Canada.—The only antimony mine in Canada was owned by Consolidated Durham Mines and Resources Ltd. It mines low-angle-dipping veins containing stibnite at its Lake George property near Fredericton, New Brunswick. The mine has four levels with the bottom level 450 feet below the surface. The mill, with an operating rate of between 150 and 200 tons per day, produced concentrates averaging over 65% antimony, which was shipped to smelters in the United States, Japan, and Europe.

India.—The Star Metal Refinery Private, Ltd., Bombay, remained the sole importer and processor of antimony ores and concentrates. Efforts to develop a domestic source of mineable antimony at Chikkannanahalli, Chitaldrug District, and Mysore was continuing.

Japan.—The Hibino Metal Co., Japan's largest antimony producer, started operation at its Banpin, Thailand, plant in June. Production started at 150 tons per month from reserves containing 500,000 tons of antimony. The company also imported 100 tons of antimony per month from Sarawak, Malaysia. The two supply sources accounted for 60% of Hibino's needs.

South Africa, Republic of.—Consolidated Murchison Ltd. operated at capacity; milling of 622,000 tons of ore provided 24,750 tons of antimony concentrate. This was slightly higher than the 619,000 tons milled in 1973, which provided 25,365 tons of concentrate. The antimony content of the concentrate averaged 60.13% in 1974.

Diamond drilling from the surface during the year totaled 10,800 feet, compared with 30,000 feet drilled during 1973. Surface drilling was confined to targets within the established mine working area, namely, from Alpha in the west to Monarch in the east, and was aimed principally at finding new ore bodies.

Antimony Products Pty. Ltd. started its new 3,500-ton-annual-capacity antimony beneficiation plant in Gravelotte, Transvaal, South Africa. Antimony Products is a joint venture of Chemetron Corp. (Chicago), Consolidated Murchison Ltd. (Johannesburg), and Johannesburg Consolidated Investment Co. Ltd. Antimony ore is upgraded by Antimony Products to an 83% crude antimony oxide prior to shipment. Chemetron received the facility's full output, approximately 25% of the output of the nearby Consolidated Murchison Mines. First shipments arrived in Chemetron's processing facility in Cleveland, Ohio, in July.

Thailand.—Progress continued on the $1.2 million antimony project located at Lampany Province (Northern Thailand) by Amco Metal Industries Corp.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Antimony content of smelter products, excludes output from New Brunswick, which is believed to be small.

[2] Antimony content of ores for export plus antimony content of antimonial lead and smelter products produced.

[3] Production by COMIBOL plus exports of medium and small miners.

[4] Total exports.

[5] Revised to zero.

[6] Antimony content of antimony concentrates, lead concentrates, and zinc concentrates.

TECHNOLOGY

A process for removing antimony impurities from blister copper or copper matte by an oxygen-enriched air technique was described in a patent.[2] Initially, iron-copper scrap, scrap iron, or other oxidizable metallic iron is added to the antimony-containing melt, and the melt is treated with oxygen-enriched air. The antimony is oxidized and attached to the iron oxide, and the insoluble oxide phase is mechanically scraped from the surface of the melt.

A detailed report on the intergranular segregation of antimony associated with temper embrittlement in a low-carbon manganese steel was published.[3]

Asbestos

By Robert A. Clifton [1]

Shipments of asbestos from mines in the United States decreased 25% from the record high in 1973. Construction industry troubles and the recession were the main reasons for the decreased demand. Imports were 3% below 1973 levels.

The world's leading producer, Canada, decreased shipments to the United States, its largest market, 3% and Canada's total 1974 shipments were 97% of 1973 shipments.

r Revised.

[1] Measured by quantity produced, plus imports, plus stockpile releases, minus exports.

Legislation and Government Programs.—The Environmental Protection Agency (EPA) published clarifications and amendments to its asbestos emission standards in May. In August, the second portion of the effluent guidelines for asbestos manufacturing point sources was published. In October EPA published some controversial proposed amendments to its national asbestos emission standards. In July the Mining Enforcement and Safety Administration promulgated amendments to its Metal and Nonmetal Mines Health and Safety Standards which substituted "fiber counts" for the former "dust counts" for asbestos mines and mills. The new standards and monitoring techniques now agree with those of the Office of Safety and Health Administration (OSHA) of the Labor Department. In 1974 the General Services Administration (GSA) reduced Government inventories by disposing of 11,586 short tons of amosite, 16,890 tons of crocidolite, and 375 tons of chrysotile. Southern Rhodesian asbestos continued to arrive in the country because of the "strategic material" exception to the U.S. observance of the United Nations sanctions.

r Revised. XX Not applicable.

Environmental Impact.—Threatened effects of environmental regulations on the asbestos manufacturing industry again failed to materialize in 1974. The small decrease in asbestos consumption was a sign of a relatively healthy industry.

The cost of coming into compliance with environmental regulations was the announced cause of the GAF Corp.'s decision to leave the asbestos-mining industry and at least somewhat of a factor in the closing of two mines in California.

On October 15 the U.S. Supreme Court let stand a lower court decision in *Borel* v. *Fibreboard Paper Products Corp., et al.* making asbestos products manufacturers and their suppliers liable for asbestos-related diseases among workers.

DOMESTIC PRODUCTION

U.S. mines shipped only 75% as much asbestos in 1974 as in 1973. The value was only 84% of the 1973 amount. Four States produced asbestos; California, with 53%, was the leader, followed in order by Vermont, Arizona, and North Carolina. Total output was 112,533 tons valued at $13,759,000.

The California segment of the asbestos industry led the sharp decline in U.S. production. The closing early in the year of the Christie mine of the Coalinga Asbestos Co., Inc. was followed by the closing of the Pacific Asbestos Corp. mine. These mine closures led to production of only 57% of the 1973 State total. Only 55% of the 1973 dollar value of the fiber was realized. At yearend negotiation was underway aimed at acquisition and reopening of the Pacific Asbestos mine. Yearend mining was limited to the Joaquin Ridge near Coalinga with Atlas Asbestos Corp. working its Santa Cruz mine in Fresno County and Union Carbide Corp. operating its Santa Rita mine in San Benito County.

GAF Corp.'s mine in Orleans County, Vt., remained the U.S. asbestos mine with the highest production; its output increased significantly over that in 1973. This mine was scheduled for closure by GAF in March 1975, but at yearend it appeared that an employee group might be successful in efforts to purchase the mine and keep it operating. Arizona production in 1974 was less than a third of the 1973 level. The Jaquays Mining Corp. mine in Gila County was the only active asbestos mine in the State. The mine in North Carolina of Powhatan Mining Co. was inactive, but some shipments from stockpile were made in 1974. U.S. asbestos producers and mine sites follow:

State and company	County	Name of mine	Type of asbestos
Arizona: Jaquays Mining Corp	Gila	Chrysotile	Chrysotile.
California:			
Atlas Asbestos Corp	Fresno	Santa Cruz	Do.
Coalinga Asbestos Co., Inc [1]	do	Christie	Do.
Pacific Asbestos Corp [1]	Calaveras	Pacific Asbestos	Do.
Union Carbide Corp	San Benito	Santa Rita	Do.
North Carolina:			
Powhatan Mining Co	Yancey	Hippy	Anthophyllite.
Vermont: GAF Corp	Orleans	Lowell	Chrysotile.

[1] Closed at yearend.

CONSUMPTION AND USES

Apparent consumption in table 1 was revised to reflect stockpile adjustments; with these adjustments it reveals a 4% decrease in overall usage.

Consumption data in table 3 were obtained from a new survey form. The new options available on the form break continuity between the 1974 data and those data in table 6 of the 1973 chapter. A benefit of the new form and computer assistance in tabulation is that end use data can now be presented by grade for chrysotile. The data in table 3 have been adjusted to agree with those in table 1.

Table 3.—Asbestos distribution by end use, grade, and type, 1974

Total	37,300	9,400	1,100	845,800

For the first time asbestos cement pipe as an end use has been isolated; it is the largest single user of asbestos with better than 26% of the total consumption. This was not unexpected, but that asbestos cement sheet would remain the third largest user at over 11% was a surprise. Flooring products at 18% were in the second spot. If the near 9% used in roofing products is added to the top three these construction industry products account for nearly two-thirds of U.S. asbestos use. The other major asbestos-using end products are friction materials at 9%, paper at 7% and coatings and compounds at 4%. Another newcomer to the Bureau of Mines survey is plastics, which uses better than 2% of the asbestos total.

Table 4 shows asbestos usage in the United Kingdom during 1973.

Table 4.—United Kingdom: Breakdown of asbestos fiber usage, 1973[1]

[1] Data furnished by Asbestos Information Association of North America.

Figure 1 shows variations in the average annual growth rate in demand over a span of years. These growth rates projected to the year 2000 can give demands ranging from 2.6 million tons down to 1.0 million tons.

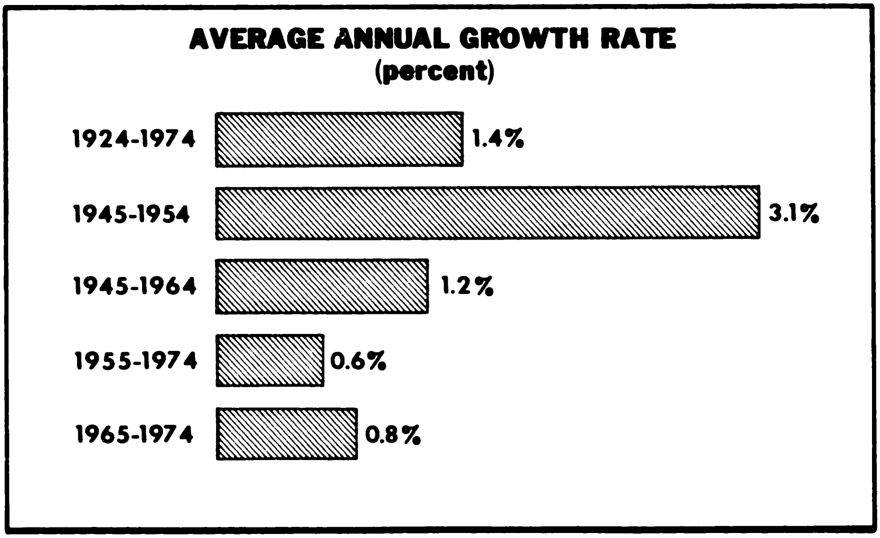

Figure 1.—U.S. asbestos demand, historical trends.

PRICES

Quoted prices for Quebec asbestos rose more than 39% during 1974 with the last rise effective on August 1, 1974. A further rise was announced effective in 1975. British Columbia asbestos prices rose more than 45% during the year in three steps, the last one also effective August 1, 1974. Another increase to start the new year was announced.

Prices for some grades of Arizona chrysotile asbestos were raised on April 1, 1974. Quotations, f.o.b. Globe, follow:

Grade	Description	Per short ton
Group No. 1	Crude	$1,750
Group No. 2	do	1,000
AAA		1,000
Group No. 3	Nonferrous filtering and spinning	$550–700
Group No. 4	Nonferrous plastic and filtering	550–600
Group No. 5	Plastic and filtering	385–425
Group No. 6	Refuse or shorts	350
Group No. 7	do	65–100

As of May 1, 1974, Vermont chrysotile asbestos, f.o.b. Morrisville, was priced as follows:

Grade	Description	Per short ton
Group No. 4	Shingle fiber	$250.00–$424.00
Group No. 5	Paper fiber	180.00–212.00
Group No. 6	Waste, stucco, or plaster fiber	131.00
Group No. 7	Shorts and floats	50.00–114.00

Quotations for Canadian (Quebec) chrysotile, f.o.b. mine, were as follows, as of August 1, 1974:

Grade	Description	Per short ton
Group No. 1	Crude	Can $2,428
Group No. 2	do	1,320
Group No. 3	Spinning fiber	$619–1,016
Group No. 4	Asbestos-cement fiber	318–576
Group No. 5	Paper fiber	214–290
Group No. 6	Waste, stucco or plaster	180
Group No. 7	Refuse or shorts	76–146

Prices for British Columbia and Yukon Territory, Canada, chrysotile asbestos were effective August 1, 1974. Quotations, f.o.b. Vancouver, follow:

Grade	Description	Per short ton
	CASSIAR MINE	
C–1	Crude	Can $2,214
AAA	Nonferrous spinning fiber	1,301
AA	do	1,034
A	do	787
AC	do	564
AK	Asbestos cement fiber	402
AS	do	349
AX	do	319
AY	do	226
AZ	do	166
	CLINTON MINE	
CP	Asbestos cement fiber	Can $380
CT	do	341
CY	do	226
CZ	do	166

African asbestos producers privately negotiate sales and this rules out market quotations. The following are averages, regardless of grade, of the values of South African imports, calculated from U.S. Department of Commerce data:

The increased demand for asbestos in all categories resulted in price increases almost across the board. Additional rises were expected early in 1975.[2]

Type	Per short ton				
	1970	1971	1972	1973 [r]	1974 [1]
Amosite	$160	$164	$187	$188	$228
Crocidolite	196	212	211	218	251
Chrysotile	198	120	202	234	282

[r] Revised.
[1] 1st 10-month data on imports, U.S. Bureau of the Census.

FOREIGN TRADE

The value of exports of asbestos products manufactured in the United States increased 48% over the value of those exported in 1973. Five of the nearly 100 countries buying these products accounted for 60% of the foreign sales. They were Canada (38%), West Germany (8%), the United Kingdom (6%), Mexico (4%), and Australia (4%).

Major groupings of exported products and their share of the total were friction products (21%), packing and gaskets (21%), asbestos cement products (18%), textiles and yarns (14%), and insulation products (8%).

In 1974 56% of the cost of imported asbestos was recovered by the exporting and reexporting of fibers and products. Only 20% of the cost of Canadian fiber was recovered from exports to Canada.

In 1974 the United States imported 91% of its asbestos needs. This was above the 1973 percentage. Canada provided better than 96% of the imports, the Republic of South Africa provided 3%, and nine other countries provided the remainder. Chrysotile, with 97%, dominated the imported types. There was a 25% increase in the dollar value of imported fibers.

WORLD REVIEW

Available information indicates that 1974 was another record year for asbestos in spite of a decline in Canadian production. Demand outstripped supply, as evidenced by a shortage throughout the year. Market growth was again limited by supply, but no real hardships surfaced, except that spinning-grade fibers were in very short supply all year. The market situation, labor problems, and worldwide inflation would indicate substantial price increases again in 1975.

An interesting comment on the world market was made by an industry publication.[3] "Directly or indirectly, the apparent consumption of asbestos is linked to comparative levels of industrialization. For instance, in the period from 1964 to 1970, North American asbestos consumption declined by 0.9% while, in the same period, demand from Western Europe grew by only 3.0%. In the developing countries, consumption rose substantially during those years: the Middle East 11.9%; Africa 16.0%; South America 9.5%; Pacific Basin countries 10.3%; and Eastern European countries and China, 18.3%."

Australia.—The Woodsreef mine was producing at a rate of about 50,000 tons per year even though Chrysotile Corp., the parent company, was in receivership.

Bolivia.—Development work on a chrysotile prospect was continuing. A truck road 87 miles long now joins the mine and the new experimental processing mill at Cochabamba.

Canada.—Even though Canadian production was 3% below the record high of 1973, it was still the second highest ever and Canada remained the world's primary producer of asbestos fiber. Significantly Quebec production was actually higher than in 1973; the drop in production came from other Provinces.

The possibility of labor problems in 1975 led to an analysis of some 1973 data released by the Bureau de la Statistique du Québec. The average production worker actually worked nearly enough hours for 52 forty-hour weeks, and was paid for even more. His annual wages were $9,516 at $4.06 per hour worked. In contrast, in 1910[4] an entire shift of 13 men in a mill had a labor cost of $24.50. Only one, the millwright, made more for the entire shift than the average worker made per hour in 1973.

With the aim of increasing manufacturing in the Province, the Minister of Resources of Quebec announced creation of a Provincial mineral marketing corporation to increase the quantity of mineral raw materials exported in a manufactured form. Asbestos was to be among the first minerals scrutinized by the corporation.

The complexities of the asbestos marketplace were described in a report[5] on one Quebec producer who offered his customers 420 grades of fiber in 1,320 different forms.

The fire that destroyed part of the King-Beaver mill of the Asbestos Corp. Ltd. on December 8 could result in the loss of 160,000 tons of fiber production in 1975, or about 30% of the corporation's total production.

United Asbestos Corp. Inc. has firm plans to bring its Midlothian mine into full production in mid-1975. This mine should add 100,000 tons per year to Canadian production.

Extensive milling and testing were still underway at the Chibougamau mine of McAdam Mining Corp., but at yearend no production decision had been announced. The Amos mine of the Abitibi Asbestos Mining Co. has scheduled production for 1978.

Cassiar Corp. announced the probable closure in 1977 of its Clinton Creek, Yukon, mine. This would mean a loss of 100,000 tons per year of production.

Colombia.—Eternit Colombiana has purchased the 70% interest of Nicolet Industries, Inc., in the Las Brisas asbestos project. The mine is now expected onstream in late 1976 and will produce a high proportion of grades 4 and 5.

Turkey.—Domestic funding is being raised to develop the rich asbestos deposits in Sivas Province.

U.S.S.R.—A midsummer Pravda article, while discussing the projected Baikal-Amur rail line which will parallel the trans-Siberian Railway from Central Siberia to the Pacific, discussed at length the natural resources in areas to be touched by the new railway. Among those discussed were large deposits of long-fibered asbestos discovered at Molodezhny. A mine and mill are planned at the site 15 miles south of the railway in the Burgat A.S.S.R.

TECHNOLOGY

The terms "asbestos," "fiber," and their composite "asbestos fiber" have been the subjects of much discussion and controversy between and among producers, users, and those interested in the health aspects of asbestos. There is some mineralogic support for several variations of the definitions. It was thought that a consensus definition, arrived at by the deliberations of a group representing all viewpoints, would have validity. Such a group, the Task Force Group on Naturally Occurring Inorganic Fibers of The American Society for Testing and Materials Committee E-34 (Toxic Substances) has proposed the following mineralogical definitions of terms relating to naturally occurring inorganic fibers to reconcile the varying viewpoints:

Asbestiform.—Mineral structured in the form of asbestos.

Asbestos.—Generic term for naturally occurring, inorganic hydrated silicates that when processed separate into flexible fibers made up of fibrils. Minerals defined as asbestos are the asbestiform varieties of the following: serpentine (chrysotile), riebeckite (crocidolite), cummingtonite (amosite), anthophyllite, tremolite, and actinolite.

Fiber.—For the purpose of this standard, fibrous particulate designates fibers, fiber fragments, and fiber agglomerates.

Fibril.—A single crystal in the form of a fiber.

Fibrous particulate.—For the purpose of this standard, fibrous particulate designates fibers, fiber fragments, and fiber agglomerates.

Naturally occurring inorganic fiber.—Form of mineral characterized by properties of flexibility and length-to-width ratio in the order of 100, composed of definite crystal unit cells oriented with respect to a specific axis.

Note 1.—The designated 100:1 aspect ratio is considered to represent a reasonable lower limit for naturally occurring inorganic fibers. Fibers of these dimensions can be broken into parts of fibers that may maintain their same surface properties and activities. Therefore, fiber fragments may have to be evaluated for atmospheric monitoring purposes. However, attempting to define a fiber by its aspect ratio alone is inadequate since it is obvious that particles of nonfibrous material do not become fibers as their aspect ratio increases through comminution.

A Bureau of Mines study to be published in 1975 compared differences between the costs of mining asbestos in the Yukon Territory, Canada, and the probable costs in nearby Alaska. The conclusion reached by the author was that 30% higher costs, due principally to labor costs, were indicated for the Alaska operation.

Late in 1973 the Materials Division of the Hitco Corp. announced a high-temperature silica fiber coated with chromium oxide.

Many substitutes for asbestos were announced in 1974. The "Saffil" alumina and zirconium dioxide fibers developed by Imperial Chemical Industries of the United Kingdom had attractive chemical and thermal properties and good filtration characteristics. Some equally attractive fibers were made by a group of Soviet scientists and others using molten basalt. A Canadian scientist[6] published the details on how to fiberize asbestos tailings to produce mineral wool.

It is significant that the proposed uses for these substitute fibers was for thermal insulation and in no case as a reinforcing agent, the most common use of asbestos, which, incidentally, was named the material having the highest ultimate tensile strength of those listed in an article for 1975 publication.[7]

Both Hooker Chemical Corp. and Diamond Shamrock Corp. announced a synthetic membrane to replace the conventional asbestos diaphragm cell in the chlor-alkali process. Commercial testing of both cell types was underway at yearend.

Union Carbide Corp. announced its new RG–600 form of asbestos which has been treated with a proprietary coupling agent that promotes better dispersion of the fiber in plastic matrices as well as increasing bonding strength between the two.

On August 15 the EPA administrator announced that the agency was conducting an investigation of the presence of asbestos in all areas of the environment and that a fiber-sampling program had been designed to study natural runoff from geologic deposits, mining and milling operations, other industrial sources, and public water supply intakes. He also announced that EPA was cooperating with several Health, Education, and Welfare organizations in launching a major animal-feeding study.

Barite

By Frank B. Fulkerson [1]

Domestic mine production of barite continued at a high level in 1974 and totaled 1.1 million tons, the same as output in 1973. Production increased 39% in Nevada, the leading barite-mining State, but output declined in Alaska, Arkansas, and Missouri. Imports of barite, mostly of crude ore, were up 6% in 1974. The domestic and imported barite was ground and used primarily as a weighting material in oil well and gas well drilling fluids. Sales of ground and crushed barite for all purposes increased 4% over those in 1973. Increased requirements for the mineral in well drilling more than offset decreased demand for other uses.

[2] **Data may not add to totals shown because of independent rounding.**

DOMESTIC PRODUCTION

Producers sold or used 1,106,000 short tons of primary barite in 1974. The term "primary barite," as used in this chapter, is defined as the first marketable product, and includes crude barite, flotation concentrate, and other beneficiated material such as washer, jig, or magnetic-separation concentrates.

---

[1] Industry economist, Division of Nonmetallic Minerals.

Barite was produced from 37 mines compared with 38 mines in 1973. There were 16 active mines in Nevada, 12 in Missouri, 2 each in Georgia and Tennessee, and 1 each in Alaska, Arkansas, California, Idaho, and Illinois. Nevada provided 69% of the quantity but only 48% of the value. Barite produced in Nevada had a relatively low value owing to transportation costs and distance to markets. The other principal barite-producing States were, in descending order of production, Missouri, Georgia, and Arkansas. The production decreases in Arkansas and Missouri were attributed to mine closures in 1973 owing to ore depletion and higher operating costs. Georgia output was about the same as that in 1973.

The leading producers of domestic barite for use in well drilling were (in alphabetical order) Baroid Div., NL Industries, Inc., with mines in Arkansas, Missouri, Nevada, and Tennessee; Dresser Minerals Div., Dresser Industries, Inc., with mines in Missouri and Nevada; and Minerals Div., Milchem, Inc., with mines in Missouri and Nevada.

Barite for chemical, glass, and filler uses was sold or used by Minerals, Pigments & Metals Div., Pfizer, Inc.; New Riverside Ochre Co.; Paga Mining Co.; De Lore Products, Industrial Chemicals Div., NL Industries, Inc.; and Industrial Chemical Div., FMC Corp.

Imported and domestic barite was ground at 11 plants located at the coastal cities of Lake Charles, Morgan City, and New Orleans, La.; and Brownsville, Corpus Christi, and Houston, Tex. Domestic barite was also ground at mills in Arkansas, California, Illinois, Missouri, Nevada, and Utah.

During the year, Milchem, Inc., completed the Argenta crushing, jigging, and grinding plant near Battle Mountain, Nev. Production at the new facility was expected to begin in 1975. In the same area, Dresser Minerals placed its new beneficiation plant at the Greystone mine in full operation. IMCO Services terminated production in April at its mine in East Northumberland Canyon, Nye County, Nev. Crude ore from a stockpile was being processed in a portable jigging plant 2 miles from the mine site that began operation in August. The concentrated ore was hauled by truck 150 miles to the end of a railroad branch line at Mina, Nev., for shipment to Houston, Tex. All Minerals Corp. shipped ore to Utah, California, and Texas from the same area of Nye County.

Dresser Minerals completed a new beneficiation plant near Blackwell, Mo.

CONSUMPTION AND USES

Nearly 87% of the ground and crushed barite sold in 1974 was used as a weighting material in oil well and gas well drilling fluids. This use increased 9%, owing to greater drilling activity. Barite used in manufacturing barium chemicals and as a filler in paints declined 5% and 8%, respectively. Other uses dropped nearly 33%. These other uses were as filler in rubber and plastics; flux, oxidizer, and decolorizer in glass manufacturing; and miscellaneous uses, including ballast for ships and unspecified industrial uses.

The statistics in table 3 are mainly for ground barite, but they also include the relatively small tonnage of crushed barite, which is used principally in the barium-chemical industry.

Barite is the principal raw material in the production of barium chemicals. The major producers of barium chemicals in 1974 were Chemical Products Corp., Cartersville, Ga.; Industrial Chemical Div., FMC Corp., Modesto, Calif.; Mallinckrodt Chemical Works, St. Louis, Mo.; and Chemical Div., Sherwin-Williams Co., Coffeyville, Kans. Sherwin-Williams also produced lithopone. By volume, barium carbonate is the most important barium chemical. It is used in the manufacture of television picture tubes, for scum control in brick and tile, in barium ferrite manufacture, and for many other purposes. Barium hydroxide is used in ceramic work, as an additive in oils and greases, and in the sugar refining process. Lithopone, produced by reacting a barium sulfide solution with zinc sulfate, is used as a white pigment.

Table 3.—Ground and crushed barite sold, by use[1]

Use[2]	1972 Quantity (short tons)	1972 Percent of total	1973 Quantity (short tons)	1973 Percent of total	1974 Quantity (short tons)	1974 Percent of total

W Withheld to avoid disclosing individual company confidential data; included with "Other barium chemicals."

[1] Only data reported by barium-chemical plants that consume barite are included.

[2] A plant producing more than 1 product is counted only once.

PRICES

Barite prices are negotiated between buyer and seller. Prices listed in trade publications serve as a general guide but do not necessarily reflect actual transactions. Price quotations reported in the Engineering and Mining Journal were unchanged in 1974 compared with December 1973 prices.

The average selling value per ton, excluding container cost of ground and crushed barite, increased from $34.67 in 1973 to $39.34 in 1974. These values were calculated from statements by producers.

Table 5.—Barite price quotations in 1974

Item	Price per short ton
Chemical, filler, glass grades, f.o.b. shipping point, carload lots:	
Hand picked, 95% $BaSO_4$, not over 1% Fe	$29.50–$31.80
Magnetic or flotation, 96% $BaSO_4$, not over 0.5% Fe	34.50
Water ground, 99.5% $BaSO_4$, 325 mesh, 50-lb bags	60.00– 80.00
Drilling-mud grade:	
Ground, 83%–93% $BaSO_4$, 3%–12% Fe, specific gravity 4.20–4.30, f.o.b. shipping point, carload lots	40.00– 47.00
Crude, imported, specific gravity 4.20–4.30, c.i.f. gulf ports	17.00– 21.00

FOREIGN TRADE

Barite exports declined 10%. Canada provided the principal market for these exports, mainly ground material, which were shipped through the following customs districts: New Orleans, 60%; Detroit, 24%; Houston, 6%; Seattle, 4%; Other, 6%.

Barite imports, comprised of 729,000

tons of crude material and 36,000 tons of ground barite, were up 6% over those of 1973. The principal sources were Peru and Ireland, followed by Mexico and Greece. Declared values per ton of crude barite at foreign ports averaged as follows for these countries: Peru, $9.95; Ireland, $11.72; Mexico, $12.06; and Greece, $14.09. Crude barite, nearly all of drilling-mud grade, entered the United States through the following customs districts: New Orleans, 44%; Laredo, 22%; Port Arthur, 20%; and Houston, Galveston, and El Paso, 14%. Ground barite was imported from Mexico.

Foreign trade statistics also showed imports of witherite, mainly from the United Kingdom. However, these statistics are open to question because there has been no reported production of witherite since the Settlingstones mine in northern England was closed in 1969. These imports could be manufactured barium carbonate instead of natural barium carbonate (witherite).

Imports of blanc fixe (precipitated barium sulfate), barium chloride, and barium hydroxide increased significantly over those of 1973. The Federal Republic of Germany, France, Italy, and the U.S.S.R. were the major sources of these imports.

WORLD REVIEW

World barite production continued at a high level in 1974. According to preliminary estimates, the United States supplied 23% of the world total.

Canada.—Nuspar Resources, Ltd., was investigating a bedded-type barite deposit discovered 130 miles northeast of Ross River in the eastern Yukon. A feasibility study, including drilling, was to be conducted in 1975.[3]

Norway.—Plans were disclosed for constructing a large barite-grinding mill at Dalen. Participants in the venture were A/S Norcem of Oslo, a cement manufacturing company, and British Ceca Co., Ltd., a chemical and drilling-mud concern. Barite was to be delivered in bulk to drilling platforms in the North Sea. The plant was to be onstream by the end of 1974.[3]

---

[3] Northern Miner (Toronto). V. 60, No. 38, Dec. 5, 1974. p. 6.

Pakistan.—Pakistan Petroleum, Ltd., and the Government of Baluchistan Province began a joint venture for mining and processing barite from a deposit near the village of Khuzdar in the Central Makran Mountain Range. The deposit is estimated to contain over 1.3 million tons of ore. It was expected that the bulk of the output would be exported. This new project should significantly increase Pakistan's barite production, which has averaged less than 5,000 tons in recent years.

Philippines.—Falcon Industrial Minerals Co. planned to establish a 1,000-ton-per-month barite mill at Mansalay, Mindoro. Production of drilling-mud-grade barite was expected to begin by yearend.[4]

Turkey.—Turkey has barred the export of crude barite. Only ground barite can now be exported.[5]

United Kingdom.—The Highlands and Islands Development Board released a report by a firm of mineral consultants on barite deposits in the Scottish highlands and islands. The consultants advised the board that areas of Sunart and Morven in northern Argyle contain barite occurrences offering best prospects for development.[6]

The port cities of Aberdeen and Dundee have become supply centers for the vessels that serve the specialized needs of oil rigs drilling at ocean depths of 500 feet and more in the North Sea. Two fully integrated supply bases have been completed at Aberdeen at which a supply vessel can dock and be simultaneously loaded with drilling mud, cement, pipe, water, and fuel for rig operations. Four other such bases are under construction at Aberdeen.[7]

TECHNOLOGY

A patent was issued on the froth flotation of barite, celestite, or similar minerals. The ore pulp was conditioned with a depressant for gangue minerals, and with a tetrasodium sulfosuccinamate compound as the collector for the values. The conditioned pulp was then subjected to flotation to concentrate the values in the froth.[8]

Bauxite

By Horace F. Kurtz[1]

The formation of the International Bauxite Association, an organization of bauxite-producing countries, and the imposition of greatly increased taxes on bauxite production by most of the countries supplying the United States were among the most significant events in the bauxite industry in 1974.

World bauxite production increased 12% to about 77 million long tons. The strong growth rate was the highest in 5 years and largely reflected increased demand for aluminum, the principal end use of bauxite. World alumina production, the intermediate step between bauxite and aluminum production, rose 9% to nearly 32 million short tons.

Bauxite and alumina production in the United States increased 4% and 3%, respectively. Imports provided over 30% of the new supply of alumina and nearly 90% of the bauxite used by domestic alumina producers.

Legislation and Government Programs.—Jamaica-type metallurgical-grade bauxite in government stockpiles was authorized for sale during 1974, but none was sold. Surinam-type metallurgical-grade bauxite sold previously was shipped from government stockpiles.

[r] Revised.

[1] Excludes calcined bauxite and bauxite imported into the Virgin Islands.

DOMESTIC PRODUCTION

The production of bauxite increased 4% to 1.95 million long tons (dry equivalent) in 1974. Arkansas produced 89% of the total. The remainder was mined in Alabama and Georgia. All of the bauxite mines were open pit operations except the Mars Hill underground mine of Reynolds Mining Corp. in Saline County, Ark.

In Arkansas, bauxite was mined by Aluminum Co. of America (Alcoa), American Cyanamid Co., and Reynolds in Saline County and by Stauffer Chemical Co. in Pulaski County. Bauxite processing plants were operated by American Cyanamid, Porocel Corp., and Stauffer.

In Alabama, bauxite was mined in the Eufaula district of Barbour and Henry Counties by Abbeville Lime Co., A. P. Green Refractories Co., Harbison-Walker Refractories, and Wilson-Snead Mining Co. The Eufaula Bauxite Mining Co., which produced in 1973, was acquired by Harbison-Walker. Drying or calcining plants were operated by A. P. Green, Harbison-Walker, and Wilson-Snead.

C–E Minerals and American Cyanamid mined bauxite in Sumter County, Ga., and operated treatment plants at Andersonville, Ga.

---

[1] Industry economist, Division of Nonferrous Metals.

Production of alumina and aluminum oxide products (excluding aluminates) at the eight alumina plants in the United States and the one plant in the U.S. Virgin Islands increased 3% to 7,812,000 short tons (7,589,000 tons calcined alumina equivalent) in 1974. The total production included 7,059,000 tons of calcined alumina, 635,000 tons of commercial alumina trihydrate, and 118,000 tons of tabular, activated, and other alumina. The output of each type of alumina except hydrate increased. Production of hydrate, which more than doubled between 1967 and 1972, declined slightly in 1973, and remained at that level in 1974.

Alumina shipments by producers totaled 7,796,000 tons (7,575,000 tons calcined equivalent) and were valued at $714 million. Calcined alumina shipments to primary aluminum plants totaled 6,766,000 tons, or 89% of the calcined equivalent of total shipments. The chemical industry, including producers of aluminum fluoride fluxes for aluminum plants, received over half of the remaining tonnage, largely as hydrate. Other shipments of alumina went mainly to producers of abrasives, ceramics, and refractories.

[e] Estimate by the Bureau of Mines.
[1] Capacity may vary depending upon the bauxite used.

CONSUMPTION AND USES

The consumption of bauxite in the United States (including the Virgin Islands) increased 1.5% to 16.9 million long tons (dry basis). Foreign sources provided 88% of the total bauxite consumed during the year. Usage increased in each of the major consuming industries.

The production of alumina and related products required 93% of the total bauxite consumed. An average of 2.06 long dry tons of bauxite was used to produce 1 short ton (calcined basis) of alumina. The two alumina plants in Arkansas used mainly bauxite mined in Arkansas, and the other seven alumina plants used only imported ore.

The refractories industry used over one-half million tons (dry weight basis) of bauxite, establishing another record high level. Nearly all of this bauxite was used in the calcined form, which weighs about 65% of the dry equivalent weight. Imports comprised 83% of the bauxite used in refractories. Refractory producers reported that 84% of their receipts of foreign bauxite came from Guyana and 12% from Surinam.

Five companies consumed bauxite in manufacturing artificial abrasives, and all of the bauxite used was imported calcined ore. About 85% of the bauxite imported by these companies during the year came from Surinam, and the remainder came from the People's Republic of China. Data on consumption by the abrasives industry included bauxite fused and crushed in Canada because much of this material is made into abrasive wheels and coated products in the United States. About 10% to 15% of this material is used for nonabrasive applications, principally refractories.

Consumption of bauxite by the chemicals industry increased 9%. The United States, Guyana, and Surinam were the bauxite sources for this industry. Other consumers of bauxite, in descending order of magnitude, included the cement, oil and gas, and steel and ferroalloys industries, and municipal waterworks.

Thirty-one primary aluminum plants in the United States consumed 9,384,000 short tons of calcined alumina, compared with 8,729,000 tons in 1973. Alumina consumption data for other uses were not available. A significant quantity was used to make aluminum fluoride and synthetic cryolite, which is also used in the production of primary aluminum.

STOCKS

Stocks of bauxite in the United States increased about 2% to 19.7 million long dry tons. The increase was attributed largely to a 700,000-ton addition to inventories of imported bauxite at alumina plants. Government stockpiles were reduced by 206,000 tons, all of which was Surinam-type bauxite shipped from defense inventories. A Government stockpile accumulated during World War II and purchased by Reynolds Metals Co. was removed from Government stockpile records and was included with data on consumers' stocks.

At the end of 1974, the Government stockpile comprised 4,638,000 tons of Jamaica-type bauxite, which was the total stockpile objective, 9,789,000 tons of Jamaica-type, Surinam-type, and refractory-grade bauxite classified as uncommitted excess (unsold), and 725,000 tons committed for sale.

Inventories of alumina and related products at plants producing alumina and primary aluminum increased 11% to 1,355,000 short tons. The Government held no stocks of alumina except in the form of abrasive grain and crude fused aluminum oxide. These stockpiles were reduced 8% to 357,000 short tons.

PRICES

Prices on most of the bauxite and alumina produced throughout the world are not quoted because the large tonnages used by the aluminum industry are usually obtained from affiliated companies or purchased under long-term negotiated contracts.

Bureau of Mines estimates of the value of domestic production were based on data supplied by producers. The Bureau's estimated average value of crude domestic bauxite shipments in 1974, f.o.b. mine or plant, was $11.01 per long ton. The average value of shipments of domestic calcined bauxite was estimated at $50.32 per ton, compared with $41.78 in 1973. Bauxite values among producers varied widely because of differences in grade.

The average value of imported dried or partially dried bauxite consumed at alumina plants in the United States and the Virgin Islands in 1974 was estimated at $23.21 per long dry ton, compared with $14.84 in 1973. Engineering and Mining Journal published the following prices on supercalcined refractory-grade bauxite imported from Guyana, car lots, per long ton:

	January–August	September–December
F.o.b. Baltimore, Md	$62.50	$87.90
F.o.b. Mobile, Ala	62.53	88.01

The average value of domestic calcined alumina shipments as determined from producers' reports was $88.59 per short ton. Shipments of alumina trihydrate averaged $84.52 per ton. The average value of imported alumina (including small quantities of hydrate), as reported by the Bureau of the Census, was $74.61 per ton at port of shipment. Exports of alumina from the United States and the Virgin Islands averaged $106.15 per ton.

Table 12.—Market quotations on alumina and aluminum compounds

(In bags, carlots, freight equalized)

Compounds	Jan. 1, 1974	Dec. 31, 1974
Alumina, calcined ---- per pound --	$0.06	$0.063–$0.069
Alumina, hydrated, heavy ---- do ----	$0.0445–.0455	.0553
Alumina, activated, granular, works ---- do ----	.1365	.1365
Aluminum sulfate, commercial, ground (17% Al_2O_3) - per ton --	67.25	72.25–93.00
Aluminum sulfate, iron-free dry (17% Al_2O_3) ---- do ----	98.60	115.60

FOREIGN TRADE

Exports from the United States classified as "bauxite and concentrates of aluminum excluding alumina" totaled 16,000 long tons in 1974 and were valued at $1.2 million. Canada received 80% of the total.

Exports of alumina, including 28,000 short tons of aluminum hydroxide, declined for the fourth successive year, to 738,000 tons. Most of the exports were shipped from domestic alumina plants to affiliated aluminum plants in Canada, Ghana, Mexico, and Venezuela. An additional 219,000 tons was exported from the alumina plant in the U.S. Virgin Islands to Norway and the U.S.S.R.

Aluminum sulfate exports doubled in 1974, rising to 42,000 short tons, valued at $1.8 million. Venezuela received 26,000 tons, and Canada received 7,000 tons. Exports of artificial corundum or fused aluminum oxide increased slightly to 32,000 tons, valued at $14.9 million. Canada, which received 10,000 tons, and the United Kingdom, which received 7,000 tons, were the leading recipients. Exports classified as "other aluminum compounds" increased to 46,000 tons and were valued at $16.8 million. Much of the tonnage was believed to be aluminum fluoride and synthetic cryolite shipped to other countries for use as a flux in making primary aluminum. Canada received 10,000 tons, Surinam 8,000 tons, Ghana 6,000 tons, and Bahrain 5,000 tons.

Total	879	65,702	765	67,078	738	77,325

[1] Includes exports of aluminum hydroxide: 1972—41,000 short tons; 1973—26,000 tons; 1974—28,000 tons.

[2] Less than ½ unit.

NOTE.—Excludes alumina exported from the Virgin Islands to foreign countries: 1972—Cyprus 26,000 tons, Norway 191,000 tons, Poland 58,000 tons; 1973—Norway 157,000 tons, the U.S.S.R. 126,000 tons; 1974—Norway 177,000 tons, the U.S.S.R. 42,000 tons.

No duties were imposed on imports of bauxite, alumina, or aluminum hydroxide in 1974. All duties on these commodities were suspended in 1971.

Imports of crude, partially dried, and dried bauxite increased 12% to 14.3 million long tons from 12.8 million tons (revised) in 1973. Jamaica provided 54% of the total, Surinam provided 20%, and the Dominican Republic provided 9%. Although imports from these three countries, traditionally the leading sources of metallurgical-grade bauxite, increased during 1974, receipts from the Boké project in Guinea provided the largest increase. An additional 761,000 tons of bauxite was imported into the U.S. Virgin Islands, largely from Guinea.

Calcined bauxite imports into the United States increased to 304,000 long calcined tons. Most of this tonnage was refractory-grade bauxite from Guyana. Additional calcined bauxite was imported into Canada for manufacture into crude fused aluminum oxide, much of which was subsequently used in abrasive and refractory products in the United States.

Alumina imports, including small quantities of aluminum hydroxide, rose 6% to a record 3.6 million short tons. Shipments from Australia provided 61% of the total and most of the increase. The remainder came largely from Jamaica, 25%, and Surinam, 13%. An additional 83,000 tons of alumina was shipped from the U.S. Virgin Islands to aluminum plants in Oregon and Washington.

WORLD REVIEW

Representatives of the Governments of Australia, Guinea, Guyana, Jamaica, Sierra Leone, Surinam, and Yugoslavia met in Guinea in March 1974 and agreed to establish the International Bauxite Association (IBA). The announced objectives of IBA included the securing of fair and equitable returns from the exploitation of bauxite resources in member countries and the securing of effective national control over their bauxite industries. Headquarters of IBA was established in Kingston, Jamaica.

The first regular meeting of IBA was held in Guyana in November. The meeting reportedly was primarily concerned with administrative business, although other matters such as bauxite and alumina pricing and taxation were discussed. The Dominican Republic, Ghana, and Haiti were admitted as new members of IBA. The 10 countries comprising IBA produced 74% of the world's bauxite in 1974 and had an estimated two-thirds of the world bauxite reserves.

World production of bauxite increased 12% in 1974. The greatest increase occurred in Guinea, and additional large increases were expected in Guinea during the second half of the decade. The rest of the increase in world production in 1974 was largely attributed to increases in the two largest producers, Australia and Jamaica, which together produced about 45% of the world total. Major output declines were in France, Malaysia, and India.

World alumina production gained 9%, as significant increases were made in Australia, Jamaica, and West Germany. Production in Japan and India declined. The United States remained the largest producer of alumina with 24% of the world total.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Austria produces alumina (fused aluminum oxide), but output is used entirely for abrasives production. Production was as follows in short tons: 1972—28,943; 1973—31,110; 1974—not available.

[2] Series revised to show calcined alumina equivalent; previous editions of this chapter have included figures on a gross weight basis.

[3] U.S.S.R. imports from Turkey; actual output may have been somewhat larger to provide raw material for an aluminum smelter due to begin operation in 1975.

[e] Estimate.

Australia.—Bauxite production in Australia, the world's largest producer, has increased from 30,000 long tons in 1962 to about 20 million tons in 1974. Alumina production has grown from 38,000 short tons to 5.4 million tons over the same period.

In 1974 Alcoa of Australia (W.A.) Ltd. operated alumina plants at Kwinana and Pinjarra in Western Australia, using bauxite from mines in the Darling Range. The capacity of the Pinjarra plant was expanded to an estimated 1.1 million short tons per year, and further expansion should increase capacity to about 2.2 million tons by the end of 1976.

The Comalco Ltd. bauxite mining operation at Wiepa, Queensland, continued to be the largest in the world. Shipments of beneficiated bauxite increased to 9.3 million tons, of which 4.0 million tons went to the Gladstone alumina plant in Queensland, 1.6 million tons to Japan, and 3.7 million tons to Europe and other areas, including 1.2 million tons to the Eurallumina S.p.A. plant in Sardinia, Italy. A second calcining kiln was completed to meet rising sales of calcined abrasive-grade bauxite. Legislation by the Government of Queensland imposed higher royalties on bauxite from Wiepa beginning in August 1974. The new regulations raised royalties 10-fold to $A0.50 on bauxite converted to alumina in Queensland and $A1.00 on exported bauxite (yearend rate of exchange: $A1.00=US$1.33). The increase was unsuccessfully challenged in the Supreme Court of Queensland.

Although labor problems at Wiepa and striking marine engineers curtailed receipts of bauxite at the Gladstone alumina plant and caused production to be cut to less than half capacity in July, alumina output for the year again exceeded designed annual capacity. It was announced that Howmet Corp., a subsidiary of Pechiney Ugine Kuhlmann (PUK), would purchase PUK's 20% direct interest in Queensland Alumina Ltd., owners of the Gladstone plant.

Nabalco Pty. Ltd., increased its production of bauxite at Gove, Northern Territory, from about 3.1 million long tons in 1973 to 3.9 million tons in 1974. Nearly half of the bauxite was exported, principally to Japan and Europe, and the remainder was used at the Gove alumina plant. Alumina production rose to 905,000 short tons.

Financing and environmental problems continued to delay the proposed Alwest bauxite and alumina project in southern Western Australia during the year. Estimates of the cost of the 1-million-ton-per-year complex rose to $500 million.

Brazil.—Extensive exploration for bauxite has taken place in the Amazon basin in recent years. Estimates of the potential of known bauxite occurrences in 1974 ranged from 2 to 5 billion tons. Three areas in which major discoveries had been made were the Trombetas area, near the confluence of the Trombetas and Amazon Rivers in the State of Pará, the Paragominas area, south of Belem and east of the Tocantins River in Pará, and the Jari area, along the southern end of the Jari River bordering the States of Amapá and Pará.

Mineração Rio do Norte, S.A., which holds the reserves discovered by Alcan Aluminium Ltd. in the Trombetas area, was expected to be the first company to produce bauxite in the Amazon basin. At yearend, production at the rate of 3.3 million tons per year by 1979 was planned. The company is owned 41% by the Government's Cia. Vale do Rio Doce (CVRD), 10% by the privately owned Brazilian company Cia. Brasileira de Aluminio, S.A., 19% by Alcan, 5% by Reynolds, and 5% each by five European companies.

CVRD also owned bauxite properties in the Paragominas area near the Belem-Brasilia highway. Other companies also held bauxite concessions in both the Trombetas and Paragominas areas. A discovery of low-iron bauxite possibly suitable for refractory use was reported in the Paragominas area.

Ethyl Corp. announced discovery of large high-grade bauxite deposits close to deep water in the Jari area of Amapá. Evaluation and engineering work on these deposits was expected to continue through 1976.

CVRD and the Light Metal Smelters Association of Japan, a consortium of five Japanese companies, agreed to form a jointly owned company, Alumínio do Brazil (Albras), to establish an aluminum complex based on bauxite from the Trombetas area. Brazilian interests would have majority ownership of Albras. The proposed complex would be located near

Belem and would include an alumina plant of 1.4 million short tons annual capacity, an aluminum plant of 660,000 tons' capacity, hydroelectric power facilities, and infrastructure.

Dominican Republic.—The Government of the Dominican Republic and Alcoa reached an accord at yearend which reportedly would more than double the revenues paid to the Government on bauxite production. The Government announced that retroactive to April 1, 1974, Alcoa would pay a royalty on bauxite production based on a rate of 5.5% of the average price obtained for primary aluminum. The announcement stated that the agreement would be provisional until Alcoa's dispute on the terms of taxation on bauxite production in Jamaica has been settled. At that time Alcoa would pay retroactive to April 1, 1974, the difference between the tax rate to Jamaica and that paid under the provisional agreement to the Dominican Republic if the Jamaican tax rate were higher. The provisional agreement also included revisions in the method of calculating earnings for income tax purposes.

French Guiana.—Alcoa announced in January 1974 that it would not go ahead with development of bauxite deposits in French Guiana, and its options were allowed to lapse.

Ghana.—The Government of Ghana and Bauxite Alumina Study Co. Ltd. (Bascol) signed a letter of intent in May concerning the development of bauxite mining in the Kibi area and the construction and operation of a 600,000-ton-per-year alumina plant. Bascol was owned by Kaiser Aluminum & Chemical Corp. and Aluminum Resources Development Co. (Ardeco), a consortium of five Japanese aluminum companies. Bascol launched a feasibility study which it expected to complete by the middle of 1975. If the project is feasible, half the output of the alumina plant would be used to supply the Volta Aluminium Co., Ltd. (Valco) smelter, and half would be exported. The Government would have a 30% equity in the complex, and Bascol would own 70%. The total cost of the project was estimated at $160 million.

Greece.—In anticipation of increased demand for bauxite, Bauxites Parnasse Mining Co., the largest bauxite producer in Greece, announced plans for expandng its mining, beneficiating, and shipping facilities. Eleusis Bauxite Mines, Inc., the second largest producer, began operation of a new bauxite dressing plant and had another under construction. The Government's bauxite export quota was increased from 1,831,000 long tons in 1973 to 3,036,000 tons in 1974 and 3,105,000 tons for 1975.

None of the proposals to construct additional alumina plants in Greece, which involved Alcoa, Reynolds, PUK, Bauxites Parnasse, and the Greek and Soviet governments, resulted in firm plans for construction by the end of 1974. Bauxite Parnasse was reportedly completing a feasibility study for a plant with annual capacity of 660,000 short tons.

Guinea.—Estimated bauxite production in Guinea increased over 100% in 1974. It was the first full year of production at the Boké project operated by Guinea Bauxite Co. (CBG), and output by this venture alone exceeded 4 million tons. CBG was owned by the Government of Guinea (49%) and Halco (51%), a consortium of aluminum producers consisting of Alcoa (27%), Alcan (27%), Martin Marietta Aluminum, Inc. (20%), PUK (10%), Vereinigte Aluminium-Werke AG (VAW) (10%), and Montecatini Edison (6%).

Bauxite was also mined by Friguia, which continued to operate the only alumina plant in Africa. Friguia was owned by the Government (49%) and Frialco Co. (51%), an international consortium consisting of Olin Corp. (38.5%), PUK (36.5%), British Aluminium (10%), Swiss Aluminium Ltd. (Alusuisse) (10%), and VAW (5%). Late in the year Olin sold its equity in Frialco to Noranda Mines, Ltd., which has a primary aluminum plant in the United States.

A third bauxite producer, the Government's Kindia Bauxite Office (OBK), began mining the deposits at Debele in the Kindia region in 1974. This project was initiated with technical assistance and financing by the U.S.S.R. All of the production, which was expected to reach 2.5 million tons per year, was to be exported to the U.S.S.R.

The Government and Alusuisse joint venture, Société Mixte Guinée Alusuisse (SOMIGA), was reportedly developing bauxite deposits in the Tougue region. Alusuisse reported that prospecting revealed over 2 billion tons of commercial-grade bauxite in this area. Another potential producer, Dabola Bauxite Co. (SBD), expected to complete feasibility studies in 1975 on its project near Dabola. SBD was a joint venture of the Governments of Guinea and Yugoslavia.

Guyana.—Bauxite was mined by Reynolds Guyana Mines, Ltd., and the Government-owned Guyana Bauxite Co. Ltd. (Guybau), which also produced alumina. Guybau reported a decline in its output of dried bauxite to 743,000 long tons, and production increases to 686,000 long tons of calcined bauxite and 348,000 short tons of calcined alumina. During the year Guybau was obtaining financing to expand its bauxite mining and calcining facilities.

In September the Government enacted legislation to impose a levy on metallurgical-grade bauxite, retroactive to January 1, 1974, similar to that enacted earlier by the Government of Jamaica. The new levy was based on a rate of 5.9% of the realized price of primary aluminum. Intentions to nationalize the Reynolds operations were announced by Government officials early in 1974. On December 31, 1974, the Government and Reynolds signed an agreement on a settlement of the levies and other taxes owed by Reynolds and the purchase of Reynolds facilities by the Government. Reynolds was to receive compensation based on the book value of its assets, approximately $14.5 million, less the agreed-upon taxes due the Government.

Haiti.—In December Reynolds Metals Co. and the Government of Haiti reached agreement on a basis for computing a severence tax on bauxite shipments for 1974. The new rate per long dry ton of bauxite was 6.3% of the average realized price per short ton of primary aluminum ingot divided by 4.32. If, for example, the average realized price of aluminum was assumed to be 34 cents per pound, the tax would be $9.92 per ton of bauxite. According to reports, a royalty of 50 cents per ton of bauxite was also applicable. Further negotiations were expected in 1975 to establish final agreement on tax rates.

Hungary.—The Government announced that the Almasfuzito alumina plant would be expanded and would reach an annual capacity of 358,000 short tons by 1976.

India.—Bharat Aluminium Co. planned to build a 220,000-ton-per-year alumina plant at Bhuj, Gujarat, with financial assistance from Iran and possible participation by the Gujarat Mineral Development Corp. The plant would produce alumina for export to Iran. A feasibility study for setting up a 550,000-ton plant to use bauxite deposits in Madhya Pradesh was being prepared by the U.S.S.R. New bauxite discoveries, potentially very large, were reported by the State of Orissa.

Ireland.—In February Alcan Aluminium Ltd. announced that it planned to construct an alumina plant, with a capacity of 880,000 tons per year, on Aughinish Island in an estuary of the Shannon River about 18 miles from Limerick. Bauxite for the plant is to be imported, mainly from West Africa, and alumina production is to be exported to other European countries. It was expected that Alcan would own at least 70% of the equity and A/S Årdal og Sunndal Verk (ASV) of Norway and Gränges Essem AB of Sweden would own the remainder. Scheduled completion of the plant was subsequently postponed from 1978 to 1980, and by yearend estimates of cost had risen to $350 million.

Jamaica.—Bauxite production in Jamaica, the world's second largest producer, increased 13%, and alumina exports increased 19%. All of the bauxite and alumina was produced by affiliates of six North American aluminum companies. In addition to the bauxite produced to supply the alumina plants on the island, Jamaican bauxite was exported, largely to plants in the United States, by Kaiser Bauxite Co., Reynolds Jamaica Mines Ltd., and Alcoa Minerals of Jamaica, Inc.

Early in 1974 the Government of Jamaica requested discussions with the bauxite producers on increasing the Government's revenues from bauxite production and on increasing the Government's control and participation in the development of Jamaica's bauxite resources. Representatives of the Government and the producers held a series of meetings but were unsuccessful in renegotiating existing bauxite tax agreements.

In June, the Jamaican Government enacted legislation imposing a new bauxite production levy, retroactive to January 1, 1974. The new levy was based on a percentage of the realized price on primary aluminum. The applicable rate was set initially at 7.5% and was scheduled to increase to 8.0% on April 1, 1975, and 8.5% on April 1, 1976. To calculate the levy on bauxite, the average realized price per ton of aluminum would be multiplied by the rate, divided by a factor of 4.3, and multiplied by the tonnage of bauxite. Estimates of the levy to be applied in 1974 ranged from $11 to $13 per ton, depending on the assumed price of aluminum. In addition to the levy, the royalty on bauxite production was increased to $0.55 per ton. Jamaican taxes and royalties in 1973 reportedly averaged about $2 per ton. The new bauxite legislation also specified minimum production levels for each producer.

The producers made quarterly payments on the required new levies, under protest, claiming violation of previous agreements on taxation. Three of the companies filed requests for arbitration with the World Bank's International Center for Settlement of Investment Disputes (ICSID). The Jamaican Government asserted that ICSID had no jurisdiction in these disputes.

In the last quarter of 1974, the Government began negotiations, on a company-by-company basis, to acquire equity participation in bauxite mining, ownership of bauxite lands, and control of mining rights. An agreement was reached with Kaiser whereby Kaiser would sell the Government at book value its bauxite lands (40,000 acres) and a 51% interest in its mining assets. The Government agreed to provide a 40-year reserve of bauxite at the current rate of extraction under a land leasing arrangement and to adjust the bauxite levy by keeping it at 7.5% for 3 years and at 1% less than the national levy for 2 additional years.

By yearend, a preliminary agreement had also been reached with Revere Jamaica Alumina, Ltd., which would provide for the purchase of Revere's bauxite land by Jamaica, a lease back of reserves, and a Government and Revere mining partnership. The Government may also participate along with six Japanese companies in a proposed expansion of Revere's Maggotty alumina plant. The alumina plant expansion by the Japanese participants would be to provide alumina for a proposed expansion of a primary aluminum plant at Scottsboro, Ala. Feasibility studies were in progress.

The Governments of Jamaica and Mexico agreed to establish an integrated bauxite, alumina, and aluminum complex as a joint venture. Announced plans included a bauxite mine to produce at least 1.3 million tons per year, a caustic soda plant, and an alumina plant of 600,000 to 800,000 tons' annual capacity, all of which will be located in Jamaica, and an aluminum smelter of 132,000 short tons' annual capacity to be built in Mexico. Jamaica will have a majority interest and Mexico a minority interest in the Jamaican facilities, and Mexico will have a majority interest and Jamaica a minority interest in the smelter.

Another bauxite-to-aluminum joint venture being studied involved Jamaica, Guyana, and Trinidad and Tobago. Bauxite and alumina would be supplied by Jamaica and Guyana, and a smelter, which would use natural gas from Trinidad for power, would be constructed at Point Lisas, Trinidad.

Japan.—Japan continued to be one of the five largest consumers of bauxite and was entirely dependent on imports for its supply. Imports declined 5% in 1974 to 5.2 million long tons. Over half of the imports came from Australia, and Indonesia and Malaysia provided most of the remainder. Alumina production by each of the three leading producers declined, but Mitsui Alumina Co. showed a slight increase. Mitsui announced that it planned to double the capacity of its alumina plant at Wakamatsu by 1976.

Philippines.—A consortium of eight foreign companies, led by Comalco Ltd. of Australia, was considering the possibility of constructing an alumina plant on Mindanao. The proposed plant would have an initial annual capacity of 880,000 short tons, would begin production in 1980, and would use bauxite from Wiepa, Australia. Comalco decided in 1973 that it was uneconomic to construct the plant at Wiepa.

Poland.—It was reported that a plant will be constructed in the province of Kielce to produce alumina from local nonbauxitic materials.[8] The plant will use the Grzymek process, developed in

---

[8] American Metal Market. Plant in Poland Will Produce Aluminum Without Using Bauxite. V. 81, No. 110, June 6, 1974, p. 13.
———. Poland Works at Its Aluminum Raw Materials Problems. V. 80, No. 135, July 12, 1973, p. 8.

Poland, which produces large quantities of cement as a coproduct.

Sierra Leone.—Alusuisse, the only bauxite producer in Sierre Leone, reported that it had confirmed substantial quantities of easily accessible bauxite in a new area near Port Loko.

Spain.—Concern about possible pollution of estuary and coastal waters by a proposed alumina plant at Villagarcia de Arosa resulted in the selection of a new plant site at San Cipriano in the Province of Lugo. The relocation was expected to delay initial production at the plant until the end of 1977. The plant will eventually have a capacity of 880,000 tons per year. It will be operated by Aluminio Español S.A., which will be owned by two Spanish aluminum companies, Empresa Nacional del Aluminio, S.A., 55%, and Aluminio de Galicia, S.A., 45%.

Surinam.—Bauxite was mined by Surinam Aluminum Co. (Suralco), an Alcoa subsidiary, and N.V. Billiton Maatschappij Suriname. Suralco also produced alumina and aluminum and converted bauxite to alumina for Billiton. Exports of bauxite, most of which was shipped to the United States, increased 3% in 1974. Alumina exports declined 11% and went largely to Europe and the United States.

In December, Suralco and the Government of Surinam signed an interim agreement which would increase bauxite revenues paid to the Government to about $10 per ton retroactive to January 1, 1974. Previous revenues from bauxite have been estimated at $2.50 per ton. Under the agreement, which was effective through 1975, the new bauxite levy will be calculated on the basis of 6% of the average annual price realized by Alcoa on unalloyed aluminum ingot.

Alcan Aluminium Ltd. and Billiton signed a joint venture agreement in July to establish a new company, Alcan Billiton Suriname N. V. (ABS), which will construct and operate a bauxite calcining plant at Smalkalden. The agreement gave the Surinam Government an option on one-third of the equity in the venture. Annual plant capacity was expected to be 150,000 tons of calcined bauxite, and production was scheduled to begin in 1976.

Reynolds Metals Co., which had been exploring for bauxite in western Surinam under a joint venture with the Government, relinquished its concession and export rights. In acquiring ownership of the venture, the Government agreed to compensate Reynolds $3.5 million.

U.S.S.R.—PUK was reported to have concluded an agreement with the U.S.S.R. to construct an aluminum complex which will include a 1-million-ton-per-year alumina plant on the Black Sea.

Yugoslavia.—Three new alumina plants were under construction in 1974. The plant of Energoinvest being built at Bacevici near Mostar, Bosnia-Hercegovina, was believed to be near completion at yearend. It will have an annual capacity of 310,000 short tons. A larger Energoinvest alumina plant of 660,000 tons' capacity was under construction at Zvornik, Bosnia-Hercegovina. This plant, which will use bauxite from Vlasenica, was expected to be completed in 1976. A third alumina plant, also scheduled for 1976, will be located at Obrovac in the northern Dalmatia part of Croatia. It will be part of the Zaton aluminum complex and reportedly will have a capacity of 330,000 tons.

TECHNOLOGY

Theories on the origin of Jamaican bauxite were reviewed.[3]

The oil embargo and subsequent increases in oil prices implemented by oil-producing countries generated considerable interest in energy consumption and conservation in all phases of the aluminum production process. Estimates of energy requirements are given in the Aluminum chapter.

Alcoa's development of fluid-flash calciners for alumina plants was described.[4] Alcoa reported that its latest model calciner requires about 1,400 Btu to calcine 1 pound of alumina, a savings of 30% to 40% in fuel requirements compared with rotary calcining kilns.

Increased costs of foreign bauxite stimulated greater interest in the development of processes to use low-grade domestic aluminum resources. Some of the nonbauxitic resources were described.[5]

---

[3] Comer, J. B. Genesis of Jamaican Bauxite. Econ. Geol., v. 69, No. 8, December 1974, pp. 1251–1264.

[4] Fish, W. M. Alumina Calcination in the Fluid-Flash Calciner. Light Metals, v. 3, 1974, pp. 673–682 (Proceedings of Sessions, 103d AIME Annual Meeting).

Reynolds Metals Co. demonstrated that alumina could be produced from domestic bauxitic laterite in existing Bayer-process plants without any alteration of the facilities. The successful demonstration was conducted at the Hurricane Creek, Ark., plant of Reynolds in March using laterite mined in 1970 at its properties in Oregon and Washington. About 3 tons of laterite was required to produce 1 ton of alumina, compared with slightly over 2 tons of bauxite. The resulting loss of capacity could be compensated by adding more digesting equipment at the beginning of the process.

A joint venture of Earth Sciences, Inc., National Steel Corp., and Southwire Co. continued tests at its Alumet pilot plant at Golden, Colo., on the recovery of alumina and fertilizer byproducts from alunite. Testing and feasibility studies were expected to be completed in 1975. Although a decision to proceed with a commercial venture had not been reached at the end of 1974, a proposed project would produce annually 500,000 tons of alumina, 250,000 tons of potassium sulfate, and 550,000 tons of triple superphosphate. The project would include the mining of over 3.5 million tons per year of alunite from extensive reserves near Cedar City, Utah. The companies involved in the project have also acquired leases on phosphate rock properties in southern Idaho and on coal in central Utah.

Alcan and PUK agreed to join in the development of a process, known as the H-Plus process, for extracting alumina from clays, shales, and other nonbauxitic raw materials. The H-Plus process uses both sulfuric acid and hydrochloric acid. A pilot plant capable of producing 20 tons of high-grade alumina per day was scheduled to be constructed near Marseilles, France, by the end of 1976.

Alcoa announced that it was expanding its research on alternate domestic raw materials and that it was considering the use of residues from coal and oil shale processing. Alcoa also held large reserves of anorthosite in Wyoming. Reports were published describing the aluminum potential of oil shales in the Piceance Creek Basin of Colorado.[6]

The Bureau of Mines in a cooperative project with industry continued its miniplant research to test and develop the most promising technologies for recovering alumina from domestic nonbauxitic resources and to provide engineering data and cost assessments for the various processes. The resources selected for testing were clay, anorthosite, alunite, and dawsonite. Other raw materials may be added. The miniplant program was based in part on a series of conjectural cost estimates for processes to recover alumina from clay and other domestic resources. These estimates were updated in June 1974[7] and require frequent review because of changing costs of energy and other materials. Eight aluminum companies joined with the Bureau in the miniplant project on a cooperative basis, effective July 1, 1974.

Miniplants to test the processes will be located at the Bureau's Boulder City, Nev., laboratory, and supporting research will be provided by other metallurgical facilities of the Bureau. The first miniplant, which was designed to process kaolinitic clay by leaching with nitric acid, was installed and operated during 1974. The second process, scheduled to begin in the latter part of 1975, will leach clay with hydrochloric acid.

Beryllium

By Benjamin Petkof [1]

Consumption of beryllium ore increased almost 7% above that of 1973. Imports of beryl decreased for the fifth consecutive year, and exports of beryllium products increased. Domestic production of bertrandite continued to provide an increasing proportion of world beryllium requirements.

Table 1.—Salient beryllium mineral statistics

	1970	1971	1972	1973	1974
United States:					
Beryl, approximately 11% BeO:					
Shipped from mines -- short tons --	W	W	W	W	--
Imports ---------------------- do ----	4,942	4,026	3,345	1,586	1,368
Consumption [1] -------------- do ----	9,496	10,373	7,781	8,695	9,279
Price, approximate, per unit BeO imported cobbed beryl at port of exportation ----------------------	$35	$33	$30	$30	$30
Bertrandite ore: Utah, low-grade, shipped from mines ----- short tons --	W	W	W	W	W
World production of beryl ---------- do ----	6,857	5,791	[r] 4,330	[r] 3,963	3,977

[r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] Includes bertrandite ore which was calculated as equivalent to beryl containing 11% BeO.

Legislation and Government Programs.—The General Services Administration removed beryl and beryllium-copper master alloy from the list of strategic and critical materials in 1973 but retained beryllium metal on the list. Although published beryllium stockpile data showed some variation from yearend 1973 to yearend 1974, no beryllium materials were released from the stockpile in 1974.

The Environmental Protection Agency (EPA) announced in the Federal Register of May 3, 1974, that beryllium emissions resulting from the incineration of sewage sludge were being studied and the EPA would determine whether it is necessary to regulate this hazardous pollutant source to provide an ample margin of safety to protect the public health.

DOMESTIC PRODUCTION

The Brush Wellman, Inc. (Brush) bertrandite mine at Spor Mountain near Delta, Utah, was the only reported domestic source of beryllium minerals in 1974.

During 1974, Brush mined enough bertrandite to maintain a 2-year supply of raw materials for its operations. In August 1974, Brush initiated a third major overburden removal program to expose additional ore for future feedstock. Completion is anticipated by mid-1975 at an estimated cost of $3.4 million. The company's beryllium facilities included plants at Delta, Utah, and Elmore, Ohio, to convert bertrandite and beryl to beryllium hydroxide. The Elmore plant also has manufacturing and fabrication facilities for beryllium metal, beryllium-copper master alloy, and beryllium oxide ceramics. Brush also conducted field examinations of several areas of potential beryllium mineralization.

---

[1] Physical scientist, Division of Nonferrous Metals.

Kawecki Berylco Industries, Inc., used imported beryl as its primary raw material. The company processed beryllium materials at its plants in Hazelton and Reading, Pa., into beryllium metal, copper master alloy, nickel, aluminum alloy, and oxide. Early in 1974, the company began operation of a new mechanical cleaning line at its Reading plant to rapidly and uniformly remove oxide films from the surfaces of beryllium-copper and beryllium-nickel strip after annealing.

CONSUMPTION AND USES

The beryllium industry consumed beryllium ore equivalent to 9,279 short tons of beryl containing 11% BeO, compared with 8,695 tons in 1973.

Beryllium metal is consumed where a high stiffness-to-weight ratio is required. The metal is used in applications such as optics, X-ray transmission windows, aircraft brakes, missile parts, and nuclear structures.

Products fabricated with beryllium-copper alloys accounted for the largest quantity of beryllium consumption. Increasing applications for these alloys were found in the business machine, appliance, transportation, and communication industries. Beryllium-copper alloys were also widely used in electrical and electronic systems for connectors, sockets, switches, and temperature- and pressure-sensing devices to provide reliability and long service life.

Beryllium oxide ceramics were used in devices such as lasers, microwave tubes, and semiconductors. Typical applications included power amplifiers for microwave and radio communications, electronic ignition systems, and power regulators.

STOCKS

Consumer stocks of hand-sorted beryl at the end of 1974 totaled 4,436 short tons, compared with 5,894 short tons at yearend 1973. Dealers' stocks of beryl were not reported.

PRICES AND SPECIFICATIONS

There were no known price quotations for domestically produced beryl. The price of available domestic beryl was negotiated between buyer and seller. Metals Week quoted the price of imported beryl at $30 per short ton unit from March to December 1974. Prior to March 1974, the price ranged from $30 to $35 per short ton unit. Published quotations for beryllium materials showed small fluctuations during 1974, and at yearend the following prices were quoted for metallic beryllium: Vacuum-cast ingot, $75 per pound; beads (97% purity), $61 per pound; powder, $56 to $63.50 per pound; and rod, $106 to $122 per pound.

Also at yearend, beryllium-copper master alloy was quoted at $59 per pound of contained beryllium metal. Beryllium-copper casting ingot (2% to 2.25% beryllium in copper) was quoted at $2.46 per pound; beryllium-copper in strip, rod, bar, and wire, $3.69 to $3.78 per pound; and beryllium-aluminum alloy ingot, $72 per pound.

FOREIGN TRADE

Exports of beryllium alloys and waste and scrap increased 32% in quantity but declined 9% in value from those of 1973. The average value of exports was $7.71 per pound in 1974, compared with $11.17 per pound in 1973 and $8.79 per pound in 1972, indicating greater quantities of scrap exported. Almost 93% of total exports were shipped to West Germany, Canada, Japan, and France.

Imports of beryl decreased for the fifth consecutive year and declined 14% in both quantity and value from those in 1973. The average value of imported beryl was $303 per short ton, unchanged from the previous year. Almost three-fourths of U.S.

imports originated in Brazil (44%), the Republic of South Africa (20%), and Uganda (10%). In addition, 20,518 pounds of wrought, unwrought, and waste and scrap beryllium metal valued at $211,302 were imported.

Table 2.—U.S. exports of beryllium alloys, wrought or unwrought, and waste and scrap [1]

WORLD REVIEW

World production of beryl increased slightly in 1974. The United States continued to make a significant contribution to the world beryllium mineral supply.

Table 4.—Beryl: World production by country
(Short tons)

[e] Estimate. [p] Preliminary. [r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] In addition to the countries listed, the Territory of South West Africa may also have produced beryl, but available information is inadequate to formulate reliable estimates of output levels.

[2] Revised to zero on the basis of official Zairian publications.

Brazil.—A paper was published describing the locations of Brazil's beryl deposits.[2]

India.—Recent reevaluations supported earlier reports that indicated the country's beryl ore reserves were sufficient for a sustained production of 2,000 tons per year. Despite this, beryl is not currently mined except as a small undeclared coproduct from mica mining or gem beryl recovery.

The Indian Government classifies beryl as a strategic mineral and regulates stocks and exports of any available beryl through its Department of Atomic Energy. This agency has control of mine production, specifications, and purchases of domestically mined beryl.

Uganda.—A recent paper described the beryl deposits of the country and techniques for their evaluation. The work led to a standard procedure for prospecting and evaluating the country's beryl deposits.[3]

TECHNOLOGY

Applications of beryllium in aerospace structures, aircraft turbines, neutron moderators and reflectors in reactors, fuel elements, neutron sources, X-ray windows, and alloys were described and discussed.[4]

A definitive review of beryllium discussing the occurrence and reserves of beryllium minerals, production of metals, alloys and compounds, international trade, uses, and prices was published.[5]

Factors affecting the strength and ductility of high-purity, hot isostatically pressed beryllium block were studied. Residual cold work was identified as the factor causing reduced ductility in the highest purity material after hot pressing. A marked increase in ductility was obtained by high-temperature annealing. Annealing between 2,200° F and 2,275° F produced hexagonal-shaped voids and decreased tensile ductility. Above 2,275° F, voids were not hexagonal and were smaller in size.[6]

A method was developed to make beryllium oxide trace determinations in biological samples. This method may find application involving long exposure to beryllium oxide emission products.[7]

Recent literature was reviewed on beryllium powder, metallurgy, melting and casting, wrought beryllium products, joining techniques, corrosion and surface treatment, purification, lattice defects, mechanical behavior, fracture, phase studies, physical and chemical properties, composite materials, properties, and applications and toxicology.[8]

Bismuth

By Charlie Wyche [1]

Sharp declines in production, consumption, and imports, unusually high prices, and increased exports characterized the domestic bismuth industry in 1974. Consumption of refined bismuth dropped some 600,000 pounds, to 21% below the 1973 consumption level, approximating the average annual amount for 1970–73. The decline in the quantity of metal used in the three major consuming categories reflected decreased availability of bismuth and the necessity of substitution under the existing market condition. A strong European demand affected world trade and resulted in a 29% decrease in domestic metal imports.

Prices fluctuated widely during the year, reaching a record high of $12 per pound by midyear. Consumer resistance, however, developed in late summer, causing a downward trend in the price to $9 per pound by yearend. World mine production showed a moderate gain because the drop in production in Japan was more than offset by increases in Mexico and Peru.

r Revised.
[1] Includes bismuth, bismuth alloys, and waste and scrap.
[2] Excludes United States.

Legislation and Government Programs.—Bismuth held in Government stocks totaled 2,100,004 pounds. Of this total, the national stockpile held 585,892 pounds and the supplemental stockpile 1,514,112 pounds. The stockpile objective is 95,900 pounds, indicating a surplus of 2,004,104 pounds which requires Congressional action for public disposal.

Exploration assistance for bismuth continued under the Office of Minerals Exploration, and Government participation remained at 75% of the exploration costs.

Federal income tax laws under the Tax Reform Act of 1969 provided a percentage depletion allowance of 22% for domestic production and 14% for U.S. companies producing from foreign sources.

DOMESTIC PRODUCTION

Domestic output of bismuth was down 13%, as production by American Smelting and Refining Company (Asarco), Omaha, Nebr., the principal producer, continued to decline. Production was again almost entirely associated with refining of domestic and foreign lead ores and bullion. The remaining small quantity of bismuth was recovered from processing leady flue dusts obtained from copper converting processes.

---

[1] Physical scientist, Division of Nonferrous Metals.

U.S. production is expected to increase significantly when The Anaconda Company's Victoria mine in Elko County, Nev., reaches full production. This is a copper mine and the bismuth content of the copper concentrate is estimated at about 0.7%. At this concentration of bismuth, an additional 400,000 pounds of bismuth could be supplied to the domestic market. UV Industries, Inc., produced no bismuth in 1974. A small quantity of metallic bismuth was obtained from secondary sources at Franklin Park, Ill., by United Refining and Smelting Co.

Domestic refinery production statistics are withheld to avoid disclosing individual company confidential data. Although domestic production is not included in tabulated world production, the United States usually ranks among the first six producing countries. The proportion of domestic production that comes from imported concentrates, bullion, and dusts can be estimated only roughly; it is probably no more than half.

CONSUMPTION AND USES

U.S. consumption of bismuth in 1974 was 2.28 million pounds, a 21% decrease in comparison with the previous year and the lowest recorded since 1971. Decreases occurred in all three major consuming categories with the most pronounced decrease in pharmaceuticals, which is composed of therapeutic agents, cosmetics, and chemical compounds. The requirements for bismuth in chemical compounds, mainly bismuth oxychloride, were down significantly, indicating possible substitution of cheaper material to obtain the pearlized or lustrous look in lipstick, eye shadows, and nail polish.

The use of bismuth as an alloy in metallurgical applications, to improve machinability of aluminum, steel, and malleable iron, dropped 19%. This was probably due to decreased production in the automobile industry.

Consumption of bismuth in fusible alloys was 20% below that of 1973, resulting from a slowdown in industrial activity and the record high selling price of bismuth during most of 1974.

New uses for bismuth were discussed by the Bismuth Institute at a meeting held in La Paz, Bolivia. An aluminum-bismuth alloy was used in doors and window frames where it retained its luster in spite of weathering effects. A process was patented in France that used bismuth to cure cattle and hogs affected with colitis.

Table 2.—Bismuth metal consumed in the United States, by use
(Pounds)

Use	1973	1974
Fusible alloys[1]	932,630	748,604
Metallurgical additives	830,928	668,982
Other alloys	15,206	21,417
Pharmaceuticals[2]	1,117,644	838,134
Experimental uses	21	305
Other uses	9,790	6,536
Total	2,906,219	2,283,978

[1] Includes bismuth contained in bismuth-lead bullion used directly in the production of an end product.

[2] Includes industrial and laboratory chemicals and cosmetics.

STOCKS

Consumer stocks of bismuth declined from 560,000 pounds at the end of the first quarter to a low of 546,000 pounds at the end of the second quarter, increased to 627,000 pounds by the end of the third quarter, and totaled 597,000 pounds at yearend. The U.S. Government sold only 57 pounds of bismuth during 1974, and Government stocks were 2,100,004 pounds at yearend.

PRICES

The producer price of refined bismuth fluctuated widely during 1974. The price was $6.50 per pound at the beginning of the year and reached a high of $12 per pound in midyear before declining to $9 per pound in August. The $9 per pound price remained in effect through yearend. Dealer prices were even more volatile, reaching a record high of $20.50 per pound before being gradually reduced.

The London Metal Exchange (LME) price for imported bismuth metal, c.i.f., was $6.50 per pound through January, but had increased to $14.00 to $14.25 by early April. After holding relatively steady through the spring months, the price began declining in June, leveling at $6.40 in late December.

FOREIGN TRADE

Exports of bismuth metal, alloys, waste, and scrap totaled 329,926 pounds, more than double those of 1973, and because of high prices the value of $1.5 million was nearly four times the 1973 figure. This was the highest export since 1970, when 910,275 pounds were shipped. Of the 24 countries that imported bismuth materials, the United Kingdom, the Netherlands, Belgium, Canada, and Austria, in declining order of receipts, accounted for about 80% of the total. Israel, Guyana, Mexico, and Argentina and 15 other small importers received the remainder.

General imports of metallic bismuth totaled 1,893,744 pounds, 29% below the 1973 level. The decline in imports was attributed to low demand resulting from record high 1974 prices. The decline of some 790,000 pounds in bismuth imports resulted from a substantial reduction in receipts from such principal suppliers as Japan, the United Kingdom, West Germany, Mexico, and Peru. Increased shipments from Bolivia, Canada, and the Republic of Korea failed to offset the decrease from the major sources. Metal imports from Australia began during the year and were expected to increase rapidly as the new Tennant Creek smelter becomes fully operational. The total value of imported bismuth metal was $15.6 million, an increase of 61% compared with that of 1973.

Table 3.—U.S. exports of bismuth [1]

Total	[r] 2,683,671	[r] 9,688	1,893,744	15,606

[r] Revised.

In addition to imports of bismuth metal, bismuth is imported as bismuth alloys, bismuth lead alloys, and bismuth compounds. Bismuth alloys with 169,000 pounds of bismuth content were received from Mexico, Canada, and the United Kingdom. Bismuth compounds totaling 42,400 pounds gross weight were received from Belgium-Luxembourg, France, Mexico, Canada, Spain, and West Germany.

WORLD REVIEW

The most significant development in the world bismuth industry was the shift from oversupply at the beginning of 1974, to a market with increasing prices and shortages in the United States by midyear, followed by a return to a supply-demand balance by yearend. Factors contributing to this unstable condition ranged from Japan's inability to obtain raw material from Australia to drastically reduced output at times by the major producers.

Also of importance was the third meeting of the Bismuth Institute held in La Paz, Bolivia, in February 1974. The Institute was formed in 1973 for the purpose of studying and promoting uses for bismuth. The information center is located in Brussels, Belgium.

[e] Estimate. [p] Preliminary. [r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] In addition to the countries listed, Brazil, Bulgaria, East Germany, and the Territory of South-West Africa are believed to produce bismuth, but available information is inadequate for formulation of reliable estimates of output levels.

[2] Production by COMIBOL, plus exports and local sales by medium and small mines.

[3] Bismuth content of refined metal, bullion, and alloys produced indigenously, plus recoverable content of ores and concentrates exported for processing.

Australia.—Mine production of bismuth in Australia reached a record 936,000 pounds in 1974. Increased output from the Peko-Wallsend Ltd. operation in the Northern Territory (N.T.) more than compensated for a decline in production at Welfram Camp. Peko-Wallsend Ltd. produced some 900,000 pounds of bismuth from three mines (Juno, Peko, and Warrego) at Tennant Creek, N.T. The increase over 1973 production was due primarily to the recovery of bismuth from copper concentrates produced at the new Tennant Creek smelter. Previously, all concentrates produced at Tennant Creek were exported, but when the copper smelter began operating in late 1973 flue dusts containing bismuth were collected for processing to bismuth bullion in the reduction plant. The plant began operation in 1974, producing a bullion containing 90% bismuth. The bullion was cast into 1-ton units and exported for refining. Ore reserves at the Juno mine as of June 30, 1973, were estimated at 110,000 tons averaging 0.80% bismuth and 60 grams of gold per ton. Reserves at the Peko mine totaled 500,000 tons of ore containing 0.15% bismuth, 3.2% copper, and 4 grams of gold per ton. At the Warrego mine, ore reserves was assessed at 5 million tons averaging 0.30% bismuth, 3 grams of gold per ton, and 2.6% copper.

Bolivia.—Bismuth production in Bolivia increased slightly to 1.43 million pounds, compared with 1.42 million pounds in 1973. The Bolivian bismuth ore is usually associated with copper and tin ores. In some areas, however, the bismuth content of ore is as high as 40%, and ore is mined primarily for its bismuth content. Most of the ore was processed at the Telamayu smelter operated by Corporación Minera de Bolivia (COMIBOL). The rich bullion produced at the plant was exported to Europe for refining. There are plans for the plant to be expanded to include a refining section to produce 99.9% bismuth metal.

Canada.—Production of bismuth, as a byproduct of smelting certain lead and zinc ores, declined again in 1974. Curtailed production of molybdenum mined in the

Malartic district of Quebec and copper ores mined near Gaspé, also in Quebec, where bismuth was a byproduct, accounted for the sharp decline. Output from lead concentrates by Cominco, Ltd., at Trail, British Columbia, and by Brunswick Mining and Smelting Corp. Ltd. at Belledune, New Brunswick, also declined. Lead and lead-zinc concentrate produced by Brunswick Mining and Smelting at its mines near Bathurst, New Brunswick, were smelted, and bismuth was produced from lead bullion.

Mexico.—Asarco Mexicana, S.A., and Metallurgica Mexicana Peñoles, S.A., were Mexico's two bismuth-producing companies during 1974. Both companies showed a slight gain in production which resulted in an overall gain of some 30,000 pounds. About half of the production was refined domestically, the remainder was exported to the United States and the United Kingdom in the form of bullion.

Japan.—Again Japan led the world in bismuth production, but output of 1.84 million pounds was down from the 1.90 million pounds produced in 1973. Japan produced a small quantity of bismuth from domestic ores, but most of the metal produced came from copper concentrates imported from Australia. With the processing of the copper concentrate in Australia, Japan's bismuth production can be expected to continue the downward trend.

Peru.—Production in Peru was 1.47 million pounds, 16% above the 1973 level. All production of bismuth was as a byproduct of copper-lead ore processing. A major part of Peru's production was exported and consumed in the United States. The remainder plus some imported concentrate from Bolivia was refined by the Cerro Corp. at La Oroya.

Boron

By K. P. Wang [1]

U.S. production and consumption of boron materials declined slightly in 1974, the first time in more than a decade. Meanwhile, exports rose to the highest level in 5 years. Output was adversely affected by a long strike, and consumption did not gain ground because of the short supply. Demand pressures were great within the United States, particularly in the glass wool area for insulation purposes related to savings in energy. Most U.S. output had been in the form of sodium borates and boric acid. In recent years, commercial production of calcium borate—first colemanite and later also ulexite—was resumed on a small scale in California, the State which provides the entire domestic production of boron minerals.

DOMESTIC PRODUCTION

Domestic production and sales of boron decreased somewhat in 1974, compared with those of 1973. As in past years, most of the output came from Kern County, Calif., and to a lesser extent from San Bernardino County, Calif.

At Boron in Kern County, the large open pit mine belonging to U.S. Borax & Chemical Corp., a subsidiary of the British-owned Rio-Tinto Zinc Corp. Ltd., remained the world's foremost source of boron. U.S. Borax produced nearly pure crude sodium borates, refined sodium borates (including anhydrous borax), and boric acid (including anhydrous boric acid) at the mine site. High-purity and specialty products were produced mainly at Wilmington, Calif., and secondarily at Burlington, Iowa. Wilmington was also the company's port of export. These plants, led by the one at Boron, had a combined annual capacity of more than 600,000 short tons of boric oxide (B_2O_3) equivalent (or about 200,000 tons of contained boron) in 1974. Crude sodium borates, known commercially as Rasorite 46 and Rasorite 65 (anhydrous variation), represented about one half of U.S. Borax's output in value and three-fifths in tonnage. U.S. Borax maintains a storage center at Botlek in the Netherlands from which borax and borates are shipped to other parts of Europe. The company's production declined only slightly during the year, despite a strike lasting for more than 4 months during which supervisory workers conducted all operations. It was found that previous production levels could be maintained with a considerably smaller work force. Late in 1974, U.S. Borax announced a program to raise output by about one-third in 3 or 4 years at a cost of $55 to $60 million.

---

[1] Supervisory physical scientist, Division of Nonmetallic Minerals.

At Searles Lake, Kerr-McGee Corp. operated the Trona plant and Stauffer Chemical Co. operated the nearby Westend plant until October 1 when Kerr-McGee bought the Stauffer plant. The former is rated at about 100,000 tons of B_2O_3 annually, and the latter at 25,000 to 30,000 tons. Borates were produced along with other chemicals such as soda ash, sodium sulfate, potassium sulfate, potassium chloride, lithium carbonate, and bromine. Kerr-McGee did not intend to disturb normal operations of the two facilities until savings can be clearly identified. Meanwhile, the high cost of energy for the distillation processes adversely affected production to some extent. The company was making headway in building its new $100 million, 1.3-million-ton-per-year soda ash plant, but costs were running much higher than original estimates. The initial plan was not to produce borates while recovering soda ash. When the new plant is completed, the soda ash part of the old plant may be scrapped, the borate part kept intact, and the salt cake part expanded.

During 1974, Tenneco Oil Co.'s Ryan mine near Death Valley, Calif., came into full operation. More reserves of colemanite were found, together with a new commercial product, ulexite. The colemanite was still shipped 30-odd miles to a plant near Lathrop Wells, Nev., where efficiency of calcining operations was greatly improved. The original designed capacity of the plant was about 70,000 tons of 48% B_2O_3-grade calcined colemanite annually, but production has been much lower, particularly in the first 2 years. The ulexite was trucked 100 miles to Dunn, Calif., where it was ground and upgraded to about a 26% to 28% B_2O_3-grade product for sale to insulating glass manufacturers. Colemanite went mainly to the tire and textile markets. The discovery of ulexite in commercial quantities expanded Tenneco's borate business.

CONSUMPTION AND USES

U.S. consumption of boron materials is difficult to estimate, because of the wide range of products and large tonnage of exports in the form of both crude and finished borates. Exports of finished borates are recorded in official U.S. trade statistics, but exports of crude borates are not. Both U.S. Borax and Kerr-McGee export considerable quantities of borates. These have to be deducted from the overall supply to evaluate what remains for consumption. Generally speaking, about half of the U.S. output of boron minerals and compounds was consumed at home, and the other half was exported. Measured in boron content (boron content of B_2O_3 is 31.1%), U.S. consumption was about 86,000 tons in 1969, 114,000 tons in 1973, and possibly 110,000 tons in 1974.

Average annual U.S. consumption of boron compounds during the last 5 years has been roughly 100,000 tons of boron content. About 40,000 to 45,000 tons goes into the manufacture of all kinds of glasses. Boron materials account for 5% to 10% of many special glasses by weight, and 50% to 75% by value. Approximately 15,000 tons per year goes into insulating fiberglass which has been gaining sharply as a consumer of boron. Roughly 10,000 tons of boron per year goes into the manufacture of enamels, frits, and glasses for protective and decorative coatings on sinks, stoves, refrigerators, and other household and industrial appliances.

Average annual U.S. consumption of boron compounds in soaps and cleansers has been about 15,000 tons of boron content including 5,000 tons in sodium perborate detergents used in high-temperature washing. Borax and boric acid uses in the cleansing field include toothpaste, mouthwash, eyewash, etc. Approximately 5,000 tons of boron yearly goes into agriculture as plant nutrients, and 2,000 to 3,000 tons goes into herbicides.

The list of miscellaneous uses has been growing: Borates as fluxing materials in welding, soldering, and metal refining; boron compounds in abrasives, especially boron nitride; boric acid as catalyst in air oxidation of hydrocarbons; boron as deoxidizer in nonferrous metallurgy, grain refiner in aluminum, thermal neutron absorber in atomic reactors, ignitor in radio tubes, and coating materials in solar batteries; direct consumption in chemicals; and boron materials for conditioning agents, plasticizers, latex paints, fire retardants, antifreeze, textiles, paper products, jet fuels, photography, and composites.

PRICES [2]

Prices for most borate products went up four times during 1974, and the two leading companies, U.S. Borax and Kerr-McGee, quoted different prices at different times. Prices went up more steeply for anhydrous products than for hydrated products, because of the high energy cost to remove water. The steep increases make it advisable to compare borate prices at the beginning and the end of the year. The rounded dollar figures quoted in table 2 are for U.S. Borax's bulk f.o.b. plant prices per short ton of product.

Table 2.—Borate prices per short ton, 1974

	Jan. 1	Dec. 31
Anhydrous borax	$110	$203
Refined pentahydrate borax	80	98
Refined decahydrate borax	60	81
Boric acid	184	199

FOREIGN TRADE

U.S. exports of boric acid were 35,740 tons valued at $8.8 million in 1974, compared with 41,407 tons in 1973. Exports of refined sodium borate, however, showed a sharp increase—to 218,107 tons valued at $33.8 million in 1974 from 168,826 tons in 1973. Thus, despite shortages at home, overall exports were higher during the year. As noted, these figures hardly tell the whole story since exports of crude borates were of the same magnitude as these of refined borates and boric acid combined.

A detailed breakdown of the recorded exports in 1974 is shown in table 3. Within this table, data for all countries outside Western Europe are fairly accurate. For Western Europe, the Netherlands is a major transshipment point rather than the final destination. A more meaningful array of recipient nations, including an estimate for crude borates, would show that West Germany, France, the United Kingdom, Japan, Belgium, Spain, and Italy were ahead of the Netherlands in that order.

In 1974, the United States imported 21,214 short tons of calcium borate (colemanite) valued at $852,000, all from Turkey. This compared with 18,216 short tons during 1973.

WORLD REVIEW[3]

Argentina.—Borate mineralization is widespread in the northwestern part of Argentina (also northern Peru), where there are desert basins called "lagunas" or "salares" having both sodium and calcium borates. The only important producer is Boroquimica Limitada, a subsidiary of Rio-Tinto Zinc Corp., which mines a Tertiary deposit in the Salas del Hombre Muerto basin. The ore from their Tincalayu mine (13,000 feet above sea level) is shipped 250 miles to the processing plant at Campo Quijano in the foothills of the Andes. Recent production has been about 50,000 to 60,000 tons of borates annually.

Turkey.—Turkey's output of borates has always been difficult to estimate, because of the varied products made and the interrelationship of the Government company Etibank and other producers. Reported statistics are generally inconclusive. As an order of magnitude, the country's 1974 production might have been approximately 250,000 tons of B_2O_3. The trend toward nationalization has brought Etibank increasingly towards the forefront, and it is this organization that is primarily engaged in the construction of new mine and plant facilities. Türks Boraks Madençilik A.S., a subsidiary of Rio-Tinto Zinc Corp., has already been relegated to a secondary position.

Extensive deposits of both tincal and colemanite are under Etibank's jurisdiction. Although details on 1974 output data are not available, Etibank's exports in 1974 consisted of about 255,000 tons of upgraded colemanite (about 40% B_2O_3 grade), 50,000 tons of upgraded tincal (perhaps 35% B_2O_3 grade), 17,000 tons of borax, and 10,000 tons of boric acid. Tincal was used to manufacture borax and boric acid at the Bandirma plant built around 1968. In addition to Etibank, six private companies together exported some 340,000 tons of colemanite in 1974.

Etibank operated two colemanite mines during 1974, the Emet open pit mine and the Espey underground mine, both in Kütahya Province and approximately 215 miles from the port city of Bandirma. A colemanite washing plant at Hisarcik with an annual capacity of just above 300,000 short tons of upgraded product (40% to 45% grade) went through its first year of full-scale operations during 1974.

---

[3] Industrial Minerals (London). Borate Supplies Still Tight Despite Rising Capacity. No. 79, April 1974, pp. 11-29.

Etibank's tincal deposits at Kirka seem to rival those at Boron in California. The grade of run-of-mine ore is about 26% B_2O_3, with traces of arsenic. A washing plant with an annual capacity of more than 400,000 tons of product (35% B_2O_3 grade) was completed in the fall of 1974. Construction of a corresponding-size downstream facility was underway and scheduled for completion by 1976. The goal is to produce 200,000 tons of Rasorite 46 (crude pentahydrate borax), 55,000 tons of Rasorite 65 (crude anhydrous borax), and 10,000 tons of refined anhydrous borax. These developments indicate that Turkey's world position as a borate supplier will be further strengthened in the future.

U.S.S.R.—The U.S.S.R. may be producing about a third of a million tons of borates annually, about one-fourth of the U.S. level. Reserves there may be of the same order of magnitude as those in the United States, although probably not as high grade. The borate industry of the U.S.S.R. has had about four decades of history, with the first discoveries made along a fracture zone of a large Permian salt dome in the Inder district north of the Caspian Sea. Subsequently, other deposits were found in Kazakhstan, the Caucasus, and several places in Siberia, including Lake Baikal. Judging from Japanese purchases of 50,000 to 60,000 tons of Soviet borates, the U.S.S.R. has had some surplus for export. This strengthens the belief that domestic consumption there is relatively low.

TECHNOLOGY

It is reported that cutting tools coated with nickel-boron alloys last 10 times longer than nickel-phosphorus-coated tools, and 3 times longer than tools coated with hard chromium.[4]

Recently, boron fluoride complexes have found widespread application as catalysts and curing agents for epoxy resin, in preparing alcohol-soluble phenolic resins, and as catalysts for coatings and laminates, for cyclization of natural rubber, and for polymerization.

Significant progress has been made in the field of boron-reinforced composites, such as boron-epoxy, boron-aluminum, boron-magnesium, and other boron composites.[5]

A new nuclear reaction, described as a fundamental departure from conventional concepts of fission and fusion that produces virtually no lingering radioactivity, has been reported by the University of California's Lawrence Livermore Laboratory. This reaction involves the proton fissioning of boron–11, with the release of copious energy that could form the basis for eventual "super clean" powerplants.[6]

Bromine

By Charles L. Klingman[1]

Toward the end of 1974, demand for bromine apparently exceeded supply, despite a modest increase in production. Two companies announced plans for expanding bromine capacity. Meanwhile, prices were increased to offset the higher costs of fuel and labor. There was a significant drop in use of ethylene dibromide, a gasoline additive. By contrast, consumption in the unclassified category ("Other compounds") rose substantially. This was probably caused by large increases in the output of new flame-retardant chemicals, although exact figures regarding these proprietary compounds were not available.

The first year for installing catalytic converters on certain new automobiles was 1974. It was quite difficult to use "leaded" gasoline, which necessarily contained ethylene dibromide, in these new cars. In addition, gasoline prices were up and consumption was down, so the net result was less ethylene dibromide used in gasoline. However, future requirements for ethylene dibromide are difficult to predict because of changing standards of the Environmental Protection Agency (EPA).

Table 1.—Elemental bromine sold as such or used in the preparation of bromine compounds by primary producers in the United States

(Thousand pounds and thousand dollars)

	1973		1974	
	Quantity	Value	Quantity	Value
Sold	39,203	7,350	45,760	12,177
Used	379,047	59,781	386,334	105,538

Total	454,405	370,850	119,688	472,284	382,646	182,142

[1] Includes hydrobromic acid, tetrabromobisphenol, ethyl, ammonium, sodium, potassium, and other bromides.

DOMESTIC PRODUCTION

The value of elemental bromine sold as such in 1974 plus the value of bromine compounds sold totaled $194.3 million, an increase of $67.3 million or 53% over the corresponding data for 1973. The substantial rise in value was due primarily to increases in price for all bromine compounds.

Overall production of bromine in 1974 increased 3.3% over that of 1973, as shown in table 1. This increase may be compared with an average annual growth rate of 6.7% over the past 14 years, and with increases of 8.7% and 8.1% in 1972 and 1973, respectively.

---

[1] Physical scientist, Division of Nonmetallic Minerals.

Arkansas production increased 7.9%, whereas Michigan and California registered declines. Arkansas produced 76% of U.S. bromine.

Approximately 10.6% of the bromine produced was sold in elemental form to nonmanufacturers of bromine compounds. There was an apparent loss of about 1% bromine when comparing the bromine used (going into compounds) with that found in the compounds after manufacture. This type of loss has averaged 1.35% over the past 5 years.

In 1974, there were 10 bromine-producing plants operated in 3 States by 7 companies. Two of these plants produced elemental bromine only, and one each produced ethylene dibromide, methyl bromide, and inorganic bromides. The remaining five plants produced a variety of compounds and elemental bromine. Two plants in Texas made compounds from purchased bromine and hence were not primary producers. Three bromine companies provided a combined total of 82% of U.S. output.

Ethyl Corp. which originally owned 80% of the Bromet Co. of Magnolia, Ark., purchased the remaining 20% of the company from Great Lakes Chemical Corp. in 1974. The name of the plant was changed from Bromet to Ethyl Corp.

Great Lakes Chemical Corp. of El Dorado, Ark., announced the construction of a new elemental bromine plant designed for additional production of 50 million pounds per year. Expenditures on the plant were estimated at $16 to $20 million.[2]

The Dow Chemical Co. also announced plans to increase bromine output at Magnolia, Ark. Expenditures will exceed $12 million.[3] Dow Chemical had a prolonged strike at its Midland, Mich., plant, but production was continued by supervisory and clerical personnel.

Table 3 lists the current bromine producers of the United States. U.S. resources are vast, although their full potential is unknown. If the rich brine sources should fail, there are unlimited reserves of dilute bromine in the oceans.

Table 3.—Bromine-producing plants in the United States

State and company	County	Plant	Production source

The Dow Chemical Co	Mason	Ludington	Well brines.
do	Midland	Midland	Do.
Michigan Chemical Corp	Gratiot	St. Louis	Do.
Morton Chemical Co	Manistee	Manistee	Do.

CONSUMPTION AND USES

The Bureau of Mines does not conduct a consumption survey of bromine and its compounds, but useful data may be derived from the production survey. The 1974 survey showed declines in the production of ethylene dibromide and methyl bromide, but a large gain in the unclassified category ("Other compounds").

Ethylene dibromide output dropped about 12% compared with a previous annual growth rate or 5.5% through 1973. The portion of the crude bromine production going into the manufacture of ethylene dibromide dropped to 58.5%. Three major factors probably contributed to this decline: (1) The general shortage of gasoline and the sharply increased price in 1974 restricted gasoline consumption, regardless of the additives used; (2) Many automobiles with catalytic converters were so constructed that it became quite inconvenient to use "leaded" gasoline (containing ethylene dibromide); and (3) there was a 5%–7% actual reduction by refiners in the concentration of additives used in gasoline. None of these factors reflected voluntary restriction by customers in the use of gasoline additives to reduce air pollution.

---

[2] European Chemical News. Great Lakes Boosts U.S. Bromine Production. V. 26, No. 655, Sept. 27, 1974, p. 22.

[3] Chemical Engineering. CPI News Briefs. V. 82, No. 1, Jan. 6, 1975, p. 136.

In December 1974, a Federal court ruled against the EPA schedule for reduction of tetraethyl lead in gasoline; EPA has appealed the ruling. In early March 1975, the director of EPA imposed a 1-year delay in the enforcement of auto exhaust standards and said that catalytic converters were causing more harm than good. The entire situation of additives in gasoline and its potential effect on the bromine industry was in a state of turmoil, and future developments are uncertain.

Methyl bromide, used primarily as an agricultural chemical, showed reductions of 12% and 8% in the past 2 years compared with a previous growth rate of about 8% per annum.

Several 1-pound cans of methyl bromide shipped by the Great Lakes Chemical Corp. of El Dorado, Ark., were found to have defective caps and were recalled from the market. The chemical is normally used as a soil sterilant and could be fatal to human beings in high concentrations.[4]

The reduced production of ethylene dibromide and methyl bromide was more than offset by a 59% increase in production of other bromine compounds. The identity of the other bromine products must be concealed to avoid revealing proprietary information, but included a variety of flame-retardant chemicals. The use of flame-retardant chemicals has shown a 7% per year growth rate that may increase to 15% per year in the next 5 years.[5]

Elemental bromine has been used as a disinfectant, algaecide, and as an oxidizer. These markets seemed to be quite stable.

PRICES

The average unit price of bulk elemental bromine, as reported by producers in 1974, was 27.24 cents per pound, an increase of 70% over the average 1973 price. This was a sharp reversal in the historic trend toward lower bromine prices.

The price of bromine in drums was increased to 62 cents per pound in November 1974.[6]

Prices quoted in the Chemical Marketing Reporter as of December 30, 1974, for bromine and some of its compounds are shown in the following tabulation:

	Value per pound (cents)
Bromine; purified	
Carlots, truckloads, delivered	**75**
Drums, carlots, truckloads, delivered east of Rocky Mountains	**55–62**
Zone I:[1] Bulk tank car, tank trucks (45,000-pound minimum), delivered	**25–30**
Ammonium bromide, national formulary (N.F.), granular, drums, carlots, truckload, freight equalized	**48.0–48.5**
Bromochloromethane, drums, carlots, freight equalized	**54.5**
Tanks, same basis	**58**
Ethyl bromide, technical, 98%, drums, carlots, freight allowed, East	**68**
Ethylene dibromide, drums, carlots, freight equalized	**25**
Methyl bromide, distilled, tanks, 140,000-pound minimum, freight allowed	**34**
Potassium bromate, granular, powdered, 200-pound drums, carlots, freight allowed	**64–77**
Potassium bromide, N.F., granular, drums, carlots	**43.5**
Sodium bromide, N.F., granular, 400-pound drums, freight equalized	**40**

[1] Delivered prices for drums and bulk shipped west of Rockies, 1 cent per pound higher. Bulk truck prices 1 cent per pound higher for 30,000-pound minimum and 2 cents per pound higher for 15,000-pound minimum. Price f.o.b. Midland and Ludington, Mich., freight equalized, 1 cent per pound lower.

FOREIGN TRADE

There was an apparent improvement in response to the 1974 Bureau of Mines survey on the exportation of bromine and its compounds. The fraction of production reported as exported rose from 9.9% in 1973 to 16% in 1974. Of the 69,346,000 pounds reported to be exported in 1974, 918,000 pounds was elemental bromine and 68,427,000 pounds was bromine contained in compounds.

Imports of bromine and its compounds remained nominal.

WORLD REVIEW

Bromine production outside the United States was about 212,000,000 pounds in 1974 compared with 432,094,000 pounds produced in the United States.

Bromine production from the United Kingdom was obtained through the Institute of Geological Sciences, London. The bromine compounds plant of Associated Octel, Ltd., in the Hale district of Manchester was closed in 1974.[7]

Israel is rapidly becoming a major producer of bromine. Bromine production there tripled in 7 years to an estimated 39.7 million pounds in 1974. Future plans call for a 50% increase in 1975, an additional 26% in 1976, and production up to 110 million pounds by 1979.[8] A company to produce bromine compounds at Be'er Sheva was founded in 1960. Its output was restricted for ecological reasons, but a new plant for compounds is to be built at Ramat Hovav, 8 miles south of Be'er Sheva. This company planned to produce 26.5 million pounds per year of compounds by 1976. The raw material for this new bromine production was the water of the Dead Sea, which contains 10,000 to 12,000 parts per million of bromine. The magnesium bromide content of the Dead Sea was estimated at 1,000 million tons.

Table 4.—Bromine: World production, by country

(Thousand pounds)

Grand total	[e] 583,352	[e] 617,089	[e] 644,294

[e] Estimate. [r] Revised.

[1] In addition to the countries listed, other nations may also produce bromine, but a reliable basis for estimation does not exist.

TECHNOLOGY

A 1974 energy survey by the Bureau of Mines revealed that approximately 5.08 kilowatt-hours or 17,300 Btu were required to produce a pound of bromine. This figure included only the direct fuel and power utilized by the wells and plants, and not the energy in the chlorine utilized nor the transportation necessary to move the bromine to its point of consumption.

Testing by the Chrysler Corp. indicated that ethylene dibromide, rather than tetraethyl lead, caused poisoning of the noble metal catalysts on automoble exhaust systems, but personnel of General Motors laboratories disagreed.[9]

Cadmium

By Ronald J. DeFilippo [1]

The trend in recent years of declining domestic production of cadmium metal continued, with output attaining its lowest level since 1946. Imported cadmium metal, not including cadmium contained in imported flue dust and zinc concentrates, provided 26% of the total U.S. supply, compared with 25% in 1973. General Services Administration (GSA) sales contributed 13% of the total U.S. cadmium metal supply. Imports of cadmium metal supplied 33% of the 1974 apparent consumption, 2% more than 1973.

Eight plants and seven companies accounted for the total domestic primary production. Canada was the major source of imported metal and ore concentrates. Producer prices increased from $3.75 to $4.25 per pound during the year.

Legislation and Government Programs.—Sales from the national stockpile (administered by GSA) were 1,006 tons in 1974. At yearend, the total stockpile inventory was 3,248 tons including 26 tons already committed. The objective for retention remained at 2,223 tons, and the quantity available for public disposal was 223 tons. Under the authority of Public Law 91–314 of July 10, 1970, a bill, S.3961, was introduced in the Congress on September 4, 1974, authorizing disposal of an additional 777 tons of cadmium from the strategic stockpile, but no further action was taken by yearend.

Exploration assistance for cadmium was offered by the Office of Minerals Exploration with 50% of allowable costs furnished by Government participation. However, no contracts were sought or active in 1974. Depletion allowances were 22% for domestic mines and 14% for mines in foreign countries.

r Revised.

[1] Primary and secondary cadmium metal. Includes equivalent metal content of cadmium sponge used directly in production of compounds.

[2] Includes metal consumed at producer plants.

[3] Average quoted price for cadmium sticks and balls in lots of 1 to 5 tons.

DOMESTIC PRODUCTION

The pace of domestic cadmium metal production slackened during the year, dropping from 958 tons during the first quarter to 685 tons during the fourth quarter. Cadmium metal production for the entire year, 3,333 tons, was down 11% from that of 1973. Metal production exceeded shipments by about 3% for 1974 and metal producer stocks increased accordingly from

---

[1] Physical scientist, Division of Nonferrous Metals.

336 tons at the end of the first quarter to 698 tons at the end of the fourth quarter. The value of shipments decreased by about 10% from those of 1973, while the tonnage of shipments decreased by 24%. The smaller reduction in value was due to price increases throughout 1974.

Cadmium sulfide production (including cadmium sulfoselenide and cadmium lithopone) decreased 23% from that of 1973 and was the lowest level since 1970. The last quarter of 1974 saw the phaseout of cadmium production at the Amax, Inc., plant at Blackwell, Okla. The Blackwell plant had ceased zinc production at the end of 1973, but had continued to produce cadmium from residue stocks throughout 1974. By 1975, Amax was to have transferred all its cadmium production to its Sauget, Ill., facility.

Smelter recovery of cadmium in the United States averaged about 12.5 pounds per ton of slab zinc produced compared with about 6 pounds per ton for the rest of the world. Preliminary assays of zinc ores encountered in the development of The New Jersey Zinc Co.'s new Elmwood zinc mine in central Tennessee indicated about 0.4% cadmium, a relatively high value.

Cadmium oxide was produced by two of the eight primary metal producing plants. One plant reported secondary production, which was remelted metal or refined cadmium sponge.

Table 2.—Cadmium sulfide [1] produced in the United States
(Short tons)

Year	Sulfide [2] (cadmium content)
1970	1,068
1971	1,118
1972	1,357
1973	1,412
1974	1,085

[1] Cadmium oxide withheld to avoid disclosing individual company confidential data.
[2] Includes cadmium lithopone and cadmium sulfoselenide.

CONSUMPTION AND USES

The apparent consumption of cadmium, 6,050 tons, fell by 3% from that of 1973. Government sales contributed 17% of the total U.S. cadmium metal apparent consumption.

Metal used for electroplating hardware in land vehicles, marine uses, aircraft, and stationary mechanical and electrical equipment accounted for slightly less than half of the total U.S. cadmium consumption. Cadmium compounds used as pigments (red, orange, yellow) in paints and plastics and stabilizer compounds used in polyvinyl chloride accounted for about one-third of the total U.S. consumption. The remainder of U.S. consumption was accounted for by cadmium metal and compounds used in alloys, nickel-cadmium batteries, and specialized electronic devices.

Total	765	561	999	570

W Withheld to avoid disclosing individual company confidential data; included with "Compound manufacturers."

PRICES

The producer price for cadmium at the beginning of the year was $3.75 per pound for 1-ton lots. On May 1, one primary producer, National Zinc Co., raised its price to $4.30 per pound. A week later, the other cadmium producers raised their prices to $4.25. Dual pricing remained in effect until December 27, when National Zinc dropped its price to $4.25; cadmium was uniformly quoted at this price by all producers by yearend. Dealer quotes were slightly below producer prices, but by the end of March, some users were reportedly paying as much as $3.90 to $4.25 per pound. With the May producer price increase, dealer prices were once again in the producer price range but dropped to as low as $4 per pound in September and continued on a downward trend throughout the fourth quarter with prices varying between $2.15 and $4. European prices began the year at about $3.65, rose to about $4.60 by late June, then fell to $2.85 to $2.15 by December after wide price fluctuations during the last half of the year.

Table 5.—Cadmium prices, 1974
(Dollars per pound)

Date	Producers' price, 1-ton to 5-ton lots
Jan. 1 to May 1	3.75
May 1 to May 7	3.75–4.30
May 7 to Dec. 27	4.25–4.30
Dec. 27 to Dec. 31	4.25

FOREIGN TRADE

Exports of cadmium metal and scrap decreased from 153 tons in 1973 to 31 tons in 1974, the lowest level since 1940, the first year export data were published in the Minerals Yearbook. Principal destinations were as follows: Canada, 28%; Switzerland, 21%; Italy, 18%; Philippines, 6%; and other countries, 27%.

Canada was again the main source of primary cadmium metal imports, accounting for 33% of the total imports followed by Australia 19%, Belgium-Luxembourg 13%, Mexico 12%, Peru 7%, and other countries 16%.

Zinc concentrate imports for consumption from which cadmium was extracted were up 13% from the 1973 level. Taking into account all imported cadmium contained in flue dust, concentrates, and cadmium metal, total imported material increased 10% from 1973 levels.

No duties were imposed on metal or flue dust imported from most favored nations, but a statutory duty of 15 cents per pound was imposed on cadmium metal from countries with centrally controlled economies, except Yugoslavia.

Table 6.—U.S. exports of cadmium metal and cadmium in alloys, dross, flue dust, residues, and scrap

[2] Less than ½ unit.

WORLD REVIEW

World smelter production of cadmium was 1% below that of 1973. Japan and the United States were the largest metal producers, with 18% each of the total, followed by the U.S.S.R. 16%, West Germany 9%, Canada 8%, Belgium 6%, and other countries 25%. Apparent consumption in the United States was 32% of the world production.

International cadmium production underwent several developments. Met-Mex Peñoles, S.A., started up its zinc smelter in Torreón, Mexico, and Akita Zinc Co. Ltd. started up a new zinc smelter at Iijima, Japan. Both smelters will have cadmium plants. Cinko Kursum Metal Sanyii A.S. of Zamanti, Turkey, announced the development of a zinc and lead refining complex that will have a capacity of about 155 tons per year of cadmium, thereby adding Turkey to the list of cadmium producers. A smelter complex underway in India, operated by Hindustan Zinc Ltd., will increase that country's cadmium smelter capacity by 110 tons per year.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Table gives unwrought metal production from ores, concentrates, flue dusts, and other materials of both domestic and imported origin. Sources generally do not indicate if secondary metal (recovery from scrap) is included or not; where known, this has been indicated by footnote. Data derived in part from World Metal Statistics (published by World Bureau of Metal Statistics, London) and from Metal Statistics (published by Metallgesellschaft Aktiengesellschaft, Frankfurt am Main). Cadmium is produced in ores, concentrates, and/or flue dusts in a number of other countries, but these materials are exported for treatment elsewhere to recover cadmium metal, therefore such output is not recorded in this table to avoid double counting.

[2] Includes secondary.

[3] Output of Tsumeb Corp. for calender years.

TECHNOLOGY

During 1974, there was continued interest in cadmium dispersal in the environment. A study of the spatial and temporal distribution of cadmium in the waters and bottom sediments of Corpus Christi Bay estuary was conducted. It was discovered that water entering the harbor was contaminated by metal-rich bottom sediments. The cadmium in the water would then be adsorbed by suspended particulate matter and thereby be distributed by the normal circulation of the bay. Similar research was being carried out in the United Kingdom.[2]

An excellent summary was prepared on the production, use, and distribution of cadmium in Canada, with some environmental considerations.[3]

The industrial sources of cadmium contamination and its effect on the environment was the subject of a brief summary. A summary of the state of the art in wastewater treatment for cadmium and other heavy metals was given.[4]

Cox, D. B. Cadmium—A Trace Element in Mining and Manufacturing. J. Environmental Health, v. 36, No. 4, February 1974, pp. 361–365.

The Environmental Protection Agency (EPA) reported that approximately 500 tons of cadmium are lost annually in sludge from the domestic electroplating industry.[5]

In the health field, research was conducted into the interaction of cadmium and other toxic materials with nutritionally important substances such as zinc.[6]

A comprehensive study of the world economics of cadmium was made in which trade, consumption, end use, smelter, and mine production of various countries were discussed.[7]

Two methods of winning cadmium values from precipitates and solutions resulting from the leaching of roasted zinc concentrates were awarded patents, and another patent was awarded for a method of cadmium recovery in the Imperial smelting process.[8]

Hydrogen embrittlement during cadmium electroplating continued to be a subject for study where plated parts requiring a high reliability are involved. A cadmium-titanium alloy that can be electrodeposited and that is not subject to hydrogen embrittlement was developed and studied.[9]

Bell Laboratories, Inc., continued its research to develop efficient yet low cost cadmium sulfide-containing photovoltaic cells. Cadmium sulfide was studied for use in masers, and in green-light-emitting diodes. In other electronic applications, cadmium telluride was found to be an excellent detector material for gamma ray and electron spectroscopy. A cadmium compound was investigated as an ingredient in photochromic glasses.[10]

The origins of a cadmium-containing stratiform lead-zinc sulfide deposit in Michigan were studied.[11]

Developments in cadmium technology are frequently abstracted in Zinc Abstracts, a bimonthly publication available from The Zinc Institute, Inc., 292 Madison Avenue, New York, N.Y. 10017.

Calcium and Calcium Compounds

By Avery H. Reed [1]

Calcium metal was manufactured by one company in Connecticut. Calcium chloride was produced by two companies in California and three companies in Michigan. Synthetic calcium chloride was manufactured by three companies in New York and Washington.

DOMESTIC PRODUCTION

Pfizer Inc., produced calcium metal at Canaan, Conn., by the Pidgeon process, in which quicklime and aluminum powder are heated in vacuum retorts; at a temperature of 1,170° C, calcium vaporizes and is collected at one end of the retort.

National Chloride Co. of America and Leslie Salt Co. produced calcium chloride from wells in San Bernardino County, Calif. Output declined 5%.

The Dow Chemical Co., Michigan Chemical Corp., and Wilkinson Chemical Corp. recovered calcium chloride from brine in Gratiot, Lapeer, Mason, and Midland Counties, Mich. Output increased 44%.

Total production of natural calcium chloride was a record high of 867,000 tons, 42% more than that of 1973 and 32% above the 1969 record high.

Allied Chemical Corp. recovered synthetic calcium chloride as a byproduct of soda ash at Syracuse, N.Y. Reichold Chemicals, Inc., recovered synthetic calcium chloride as a byproduct of pentachlorophenol manufacture at Tacoma, Wash., and Hooker Chemical Corp. manufactured calcium chloride at Tacoma using limestone and hydrochloric acid. Total output of synthetic calcium chloride decreased 6% to 234,000 tons, 44% below the 1968 record high.

The total value of all calcium chloride sold in 1974 was a record high of $36.1 million.

CONSUMPTION AND USES

Calcium metal was used as a reducing agent to separate metals such as columbium, tantalum, thorium, titanium, uranium, vanadium, and zirconium from their oxides; to form alloys with aluminum, lead, lithium, magnesium, and silicon; as a scavenger in the steel industry; and in the manufacture of calcium hydride. A potentially important use for calcium metal is in a new storage battery that requires no water to be added.

The principal use for calcium chloride was to melt snow and ice from roads, streets, bridges, and pavements. Calcium chloride is more effective at lower temperatures than rock salt, and is mainly used in the Northern and Eastern States. It was also used to keep down dust on roads and driveways, and as an accelerator for concrete.

---

[1] **Supervisory physical scientist, Division of Nonmetallic Minerals.**

PRICES AND SPECIFICATIONS

Prices for calcium metal ranged from \$1 to \$5 per pound. Calcium chloride is usually sold either as solid flake or pellet averaging about 75% $CaCl_2$, or as a concentrated liquid averaging about 40% $CaCl_2$. On a 75% basis, the average value in 1974 for natural calcium chloride was \$33.66 per ton; and the average value for synthetic calcium chloride was \$29.40 per ton.

FOREIGN TRADE

Exports of calcium chloride, mainly to Canada and Mexico, were 30,900 tons valued at \$1,699,000, compared with 96,900 tons valued at \$2,225,000 in 1973. Exports of dicalcium phosphate, mainly to Mexico, Malaysia, People's Republic of China, and Thailand, totaled 29,200 tons valued at \$6,864,000. Exports of precipitated calcium carbonate, mainly to Canada, Singapore, and South Vietnam, were 11,100 tons valued at \$1,541,000.

Total imports of calcium and calcium compounds were 239,000 tons valued at \$16,899,000. Imports of calcium metal from Canada, France, and the U.S.S.R. totaled 55 tons valued at \$121,000. Imports of calcium chloride, mainly from Canada, were 3,600 tons valued at \$156,000, 51% below those of 1973. Imports of other calcium compounds, mainly from Norway, Turkey, Italy, Canada, and the Netherlands, were 235,000 tons valued at \$16,623,000.

Imports of other calcium compounds included 155,244 tons of calcium nitrate from Norway, Italy, the Netherlands, Sweden, Denmark, Canada, and New Zealand; 34,181 tons of whiting from France, Switzerland, the United Kingdom, Belgium-Luxembourg, and Italy; 21,214 tons of calcium borate from Turkey; 6,515 tons of dicalcium phosphate from Israel, Canada, the Netherlands, and West Germany; 3,563 tons of calcium carbide from Canada and Belgium-Luxembourg; 3,345 tons of precipitated calcium carbonate from the United Kingdom, Japan, Brazil, France, the Netherlands, West Germany, and Canada; 3,127 tons of calcium cyanamide from West Germany, Canada, and Japan; 1,935 tons of calcium cyanide from Canada; and 5,972 tons of other compounds, mainly from the United Kingdom, the Netherlands, and West Germany.

Table 1.—U.S. imports for consumption of calcium and calcium chloride

Year	Calcium		Calcium chloride	
	Pounds	Value	Short tons	Value
1970	164,769	\$141,125	8,280	\$359,096

WORLD REVIEW

Canada.—Chromasco Corporation Limited produced calcium metal at its Haley smelter near Renfrew, Ontario. Canada continued to lead all other countries in the production of calcium metal. About 48 tons valued at $98,000 was exported to the United States. Canada was the leading source of U.S. imports of calcium chloride.

France.— Planet Wattohm S.A., a subsidiary of Compagnie de Mokta, produced calcium metal by the Pidgeon process. About 6 tons valued at $22,000 was exported to the United States.

U.S.S.R.—Some calcium metal was produced in the U.S.S.R. Nearly 1 ton of Soviet calcium metal valued at $1,100 was exported to the United States.

Carbon Black

By John L. Albright [1]

Demand for carbon black was strong during the first half of 1974 but fell during the second half of the year, owing mainly to reduced demand for automobile tires. Carbon black was utilized by numerous industries, but most of the production was used in transportation vehicle tires and related automobile industry rubber products. Producers encountered increased costs for natural gas and liquid hydrocarbon feedstocks and reported that carbon black prices failed to keep pace with spiraling costs. Texas produced more carbon black than any other State, and Louisiana maintained its position as the country's second largest producer. Furnace black production declined 2.7% from the 1973 output. Production of channel blacks continued its downward trend, and by yearend 1974 channel black production in the United States was restricted to one Cities Service Co. plant in Texas.

Shipments, including exports, of carbon black totaled 3,324 million pounds. Domestic shipments fell to 3,123 million pounds, after 3 consecutive years of increases. Total exports of channel and furnace blacks increased 9 million pounds, reaching nearly 202 million pounds by yearend. Imported carbon black totaled 29.6 million pounds and was supplied mainly by Canada, Indonesia, and West Germany. Small quantities of bone black were imported from Canada and West Europe, and some lampblack was imported from West Germany.

According to Chemical Marketing Reporter, channel black prices were stable during the year, but prices of most grades of furnace black increased 35% to 68%, reflecting mainly large increases in feedstock costs. Prices of thermal blacks recorded the largest increases.

Numerous grades of carbon black were shipped to ink, paint, rubber, and several other small industries, and the rubber industry continued to consume the largest quantities of carbon black. Most of the carbon black was used in the manufacture of highway vehicle tires and other automobile industry products. The 1974 slowdown in carbon black production and shipments mirrored the performance of the tire industry. According to the Rubber Manufacturers Association, Inc., 175.7 million motorcycle and passenger tires were produced in 1974 (a decrease of 7.1% from the previous year), and shipments of these tires fell 26.8 million units to 175.2 million units during 1974. Production of bus and truck tires increased 4.3% to 35.7 million units in 1974, although shipments of these tires fell 2.6 million units to 34.2 million units during 1974.

Carbon-black-producing plants operated at 78.98% of capacity during 1974, a significant decrease from the 82.85% of capacity in 1973. Plant capacity increased 1.6% from that of 1973. More than three-fourths of the capacity was in Louisiana and Texas.

During August, Continental Carbon Co. assumed the marketing of its carbon blacks and established its domestic sales headquarters in Akron, Ohio. Continental's carbon blacks had previously been marketed by Witco Chemical Corporation. Phillips Petroleum Co. established its worldwide carbon black marketing office in Akron during the year.

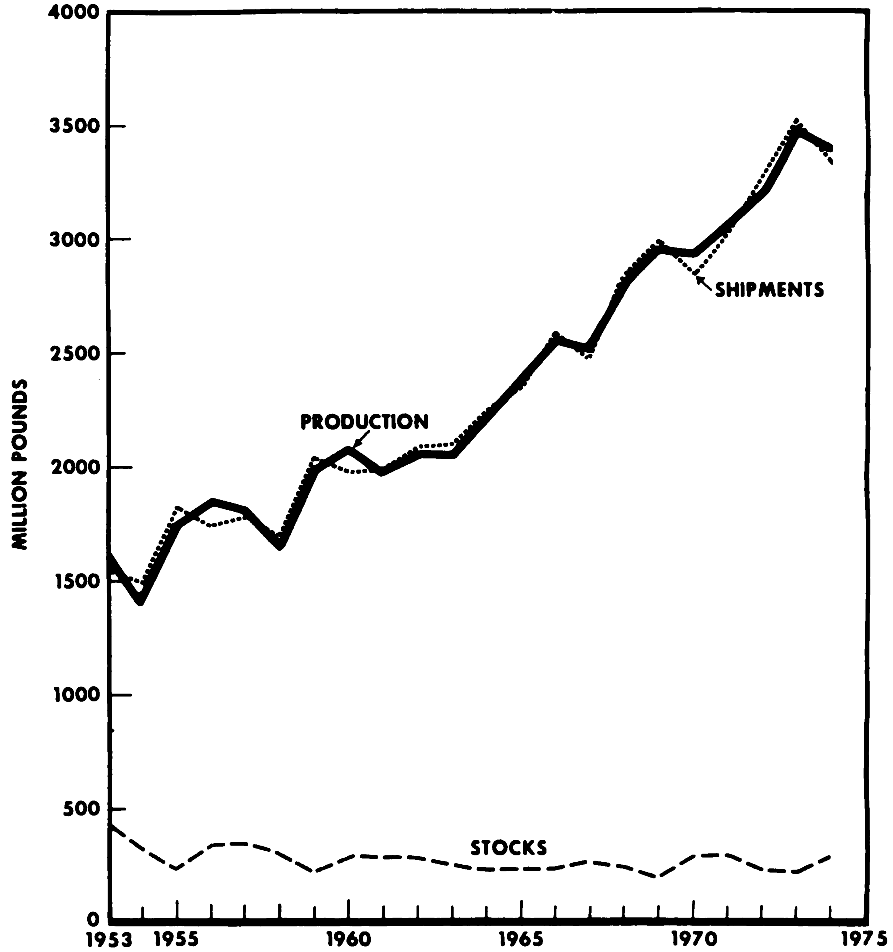

Figure 1.—Production, stocks, and shipments of carbon black.

PRODUCTION AND CAPACITY

Production by State.—Carbon black production totaled 3,390 million pounds of furnace black during 1974, plus an undisclosed amount of channel black; the industry produced a record 3,500 million pounds of channel and furnace blacks in 1973. Plants in Louisiana and Texas produced an aggregate of 2,628 million pounds of furnace black in 1974, or 77.5% of the national total, and the remaining output came from plants in Arkansas, California, Kansas, Ohio, Oklahoma, and West Virginia.

Production by Grade and Type.—All of the reported carbon black output was obtained by furnace combustion and thermal cracking methods, but small quantities of channel blacks were also produced during the year. Channel black production has fallen sharply during the past decade and dropped from 113.5 million pounds in 1970 to 14.2 million pounds in 1973. The combined production of Fast-Extrusion Furnace (FEF), General-Purpose Furnace (GPF), and High-Abrasion Furnace (HAF) grades accounted for nearly three-fourths of the 1974 furnace black production.

Number and Capacity of Plants.—Thirty-four carbon black plants operated in the United States in 1974, but during the year Cabot Corp. closed its Texas channel black plant and Continental Carbon Co. closed its Alabama furnace black plant. More than three-fourths of the installed plant capacity was in Louisiana and Texas. The total daily capacity of carbon black plants reached 11.8 million pounds in 1974, an increase of 16% from the previous year and 17.2% during the period 1969–74.

Cities Service Co. increased the capacity of its Franklin, La., plant and installed dual supply lines at the company's plants to permit boilers and dryers to be fueled by natural gas or oil. Cities Service continued to operate its Texas channel black plant, but reduced the number of specialty grades produced at the facility. J. M. Huber Corp. developed plans which will raise the firm's annual output capacity by 30 million pounds.

During 1974 Phillips Petroleum Co. had authorized, or under construction, carbon black production expansions at its Borger and Orange, Tex., and Toledo, Ohio plants. When completed, the new units will provide an additional 57 million pounds of annual capacity to the company's domestic output. After installing a computer at its Borger, Tex., plant to control output of several reactors, Phillips reported a higher degree of continuous quality control and economies in feedstocks used. The computer regulates the tangential gas input on the basis of caloric content rather than mass or volumetric flow and maintains a continuous heat balance around each reactor.

Materials Used and Yields.—In 1974, a total of 578.8 million gallons of liquid hydrocarbons was used in the manufacture of 3,209 million pounds of carbon black, after the industry had consumed a record 623.2 million gallons of liquid hydrocarbons in the previous year. Yields averaged 5.54 pounds per gallon from the liquid hydrocarbons, compared with 5.22 pounds per gallon in 1973. Natural gas feedstocks continued their downward trend, decreasing by 9,552 million cubic feet to 40,130 million cubic feet in 1974. The volume of carbon black produced from natural gas was 181 million pounds, a decline of 65.3 million pounds, or 26.5% from the 1973 production. Yields of carbon black from natural gas in 1974 averaged 4.51 pounds per thousand cubic feet, a decrease of 9.1% from that of 1973.

CONSUMPTION AND USES

The rubber industry used over 92% of the carbon black consumed. Tire manufacturers, the principal consumers, have found the commodity's remarkable ability to reinforce and strengthen rubber virtually indispensable to their industry. Automobile passenger tires used 6 or 7 pounds of carbon black each, and truck tires used approximately 20 pounds of blacks each. After 3 consecutive years of growth, domestic sales of carbon black fell 5.0% to 3,147 million pounds in 1974, due mainly to the recession which held down the production and sales of automobiles and tires. During 1974, sales to rubber manufacturers fell by 6.1%, while sales to paint and paper manufacturers decreased by 12.6% and 14.4%, respectively. Sales to the ink industry fell 1.4 million pounds to 83.0 million pounds during 1974.

STOCKS

Yearend 1974 furnace black stocks were 293.9 million pounds, an increase of 65.9 million pounds or 28.9% above the 1973 inventory. The 1974 yearend inventory was the industry's largest in 3 years. Channel black stocks were not reported by the industry during the year.

Significant increases in stocks were reported in thermal and FEF blacks, which were both at low levels in January. Stocks of most furnace grades increased slightly during the year. Inventories of HAF were maintained at the highest level of all grades of carbon black, and represented 36.9% of the total furnace black stocks at yearend.

FOREIGN TRADE

Exports of carbon black increased 9.1 million pounds to 201.7 million pounds in 1974. Furnace blacks accounted for 95.7% of the exports, and although channel blacks made up only 4.3% of the exports, they accounted for $6.1 million (18.4%) of the $32.9 million total value of the exported blacks. Average value of the channel blacks exported in 1974 was 69.2 cents per pound (49.9 cents per pound in 1973), and that of furnace blacks was 13.9 cents per pound (9.3 cents per pound in 1973). Nearly 68% of the carbon black exports went to Asia and Europe, with Japan and France purchasing the largest quantities.

Carbon blacks imported into the United States during 1974 totaled 29.6 million pounds, an increase of 19.9 million pounds from 1973 imports. During 1974, the volume of imported blacks from Indonesia rose 32.7%, and imports from Canada increased 414%. In 1974, imported carbon blacks were valued at an average 14.6 cents per pound, compared with 16.3 cents for exported carbon blacks; the corresponding 1973 values were 11.4 and 12.5 cents per pound, respectively.

In 1974, West Germany shipped 25,000 pounds of lampblack valued at $4,500 to the United States, and 91,354 pounds of bone black valued at $13,000 was imported from Belgium-Luxembourg, Canada, and West Germany.

WORLD REVIEW

The United States, Japan, and West Germany were the three largest manufacturers of carbon black, accounting for more than one-half of the known world production. Worldwide demand for carbon black was strong in 1974, and significant expansions to producing plants were authorized or under way in numerous countries.

In an effort to meet the demand for carbon black in Australia, a subsidiary of Phillips Petroleum Co. approved plans to enlarge the capacity of the Kurnell carbon black plant by 6.6 million pounds per year.

During 1974 motor vehicle production increased significantly in Brazil, and several tire manufacturing facilities and a carbon black plant were being enlarged to meet increasing demand. A subsidiary of Firestone Tire and Rubber Co. expanded tire manufacturing facilities at Rio de Janeiro and São Paulo, and a Goodyear Tire and Rubber Co. subsidiary planned to double the capacity of the Americana tire plant near São Paulo. Companhia Petroquimica Brasileira—with major interests held by Cities Service Co. —increased the capacity of the São Paulo carbon black plant to 130 million pounds per year. The Cabot Corp., International Finance Corp., and União de Industrias Petroquimicas, S.A. were planning to construct a carbon black plant at Capuava, also near São Paulo.

Commercial production began at the Cancarb Ltd. thermal black plant in Medicine Hat, Alberta, Canada, and the firm studied plans to increase the output of the facility in the near future. Approximately one-half of the Cancarb thermal black was marketed in Canada and the United States, and the balance was shipped to Australia, Japan, Latin America, and Western Europe. The Bristol, England, carbon black plant, jointly owned by Cities Service Co. and Phillips Petroleum Co., added production units which boosted its annual capacity by 8.8 million pounds. India increased the annual capacity of the

Durgapur plant by 4.4 million pounds, an extension to the Ravenna, Italy, carbon black plant raised its annual production capacity by 11 million pounds, and additional production units were installed at the Port Elizabeth, Republic of South Africa, facility, raising the output capacity by 17.6 million pounds per year.

TECHNOLOGY

Carbon black, a petrochemical, is an extremely fine soot, primarily carbon (90% to 99%), that contains some hydrogen and oxygen. Oil furnace black may also contain small amounts of sulfur. Properties of carbon black are determined largely by the process by which it is manufactured. Furnace black, which accounts for 99% of all carbon black produced, is made by three different processes—gas furnace, oil furnace, and thermal. Brief descriptions follow of these processes, the channel process, and the manufacture of lampblack and acetylene black.

Gas Furnace.—The gas furnace process is based on partial combustion of natural gas in refractory-lined furnaces. Carbon black is removed by flocculation and high-voltage electric precipitators. Yields of the gas furnace blacks range from 10% to 30% and are the lowest for the smaller particle-size grades. Properties of gas furnace blacks can be modified to a degree by changing the ratio of air to gas. High-Modulus Furnace (HMF) and Semireinforcing Furnace (SRF) grades are generally produced from gas.

Oil Furnace.—Liquid hydrocarbons are used in the oil furnace process. Natural gas is generally burned to furnish the heat of combustion, and atomized oil is introduced into the combustion zone to be burned to various grades of carbon black. Yields range from 35% to 65%, depending on the grade of black produced. Oil furnace grades are FEF, GPF, HAF, Intermediate-Abrasion Furnace (ISAF), and Superabrasion Furnace (SAF).

The most desirable feedstock oil for furnace black plants has 0° to 4° API gravity, is low in sulfur, and is high in aromatics and olefins. It comes from near the "bottom of the refinery barrel" and is similar in many respects to residual fuel oil. Rising costs of natural gas have influenced the shift to a greater use of liquid feedstocks and a corresponding decline in the use of natural gas as a source of carbon. Oil furnace processing has become highly flexible, supplementing channel blacks in most high-performance applications, notably passenger car tires. Over the past 2 decades, carbon black technology has centered on the oil furnace black process.

Thermal.—Unlike channel and the gas and oil furnace blacks, thermal blacks are produced by cracking hydrocarbons, that is, by separating carbon from the hydrogen and not by the combustion of hydrocarbons. Thermal furnaces are built in a checkerboard brickwork pattern. Two refractory-lined furnaces, or generators, are used. One generator is heated using hydrogen as a fuel, while the other is charged with natural gas, which decomposes to produce thermal black and hydrogen. Hydrogen collected is used as fuel for the generator being heated. Yields of carbon black range from 40% to 50% and are primarily in the large particle sizes.

Channel Black.—Made by the oldest process, channel black is a product of incomplete combustion of natural gas. Small flames are impinged on cool surfaces, or channels, where carbon black is deposited and then scraped off as the channel moves back and forth over a scraper. Properties of channel black are varied by changes in burner tip design, distances from tip to channel, and the amount of air made available for combustion. The process is extraordinarily inefficient chemically. For rubber-reinforcing grades, the yield is only 5%; for high-color blacks of finer particle sizes, the yield shrinks to 1%. Low yields and rising gas prices have spurred the industry to develop other methods to make blacks.

Lampblack.—Lampblacks are manufactured by slowly burning selected oils and tars in a restricted supply of air. These blacks are of large particle size, possess little reinforcing ability in rubber, and are low in jetness and coloring power. They are of value as tinting pigments in certain paints and lacquers. In most applications lampblacks have been replaced by carbon blacks.

Acetylene Black.—Acetylene blacks, produced by the thermal decomposition of acetylene, possess a high structural, or chaining, tendency. They provide high elastic modulus and high conductivity in rubber stocks.

Coal-derived carbon blacks have yet to be produced commercially, but several small companies are marketing carbon black extenders and fillers which are produced from anthracite and bituminous coals. These carbon black substitutes are used in rubber compounding and in the production of carbon paper, ink, paint, and plastic. Extenders (fillers from coal) are being utilized in conjunction with furnace carbon blacks, replacing thermal blacks.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, the People's Republic of China, Norway, Poland, Turkey and the U.S.S.R. produce carbon black, but production is not reported, and available information is inadequate to make reliable estimates of output levels.

[2] Less than ½ unit.

Cement

By Brinton C. Brown [1]

Portland cement shipments from plants in the United States and Puerto Rico in 1974 totaled 79,482,000 tons, a decrease of 8% below the record 1973 shipments and the lowest since 1971. Despite curtailed output, profits and return on investment improved after price controls were removed in late 1973 by the Cost of Living Council. Mill value for portland cement rose to $2.1 billion, an increase of 11% over 1973, reflecting a unit value increase of $4.64 per ton.

The cement situation in the United States in 1974 was one of restricted demand, increased production capacity, and escalating production costs (caused mostly by inflation and rising fuel and power costs), but price increases were adequate to compensate for these increases.

In an effort to curb spiraling inflation, the Federal Reserve Board took restrictive action on the money supply that led to record high interest rates. As a result of the tight money market and high interest rates, a broad decline in most types of construction occurred, with a sharp downturn in housing construction.

Atlantic Cement Co., Inc. completed an air-quality-control project at its Ravena, N.Y. plant, and was cited in 1974 by the American Lung Association and by the New York Department of Environmental Conservation for achievements in air quality control.

Louisville Cement Co. led Portland Cement Association members competing for the 1974 Safety Contest Awards, with 9 consecutive years without a lost-time accident.

p Preliminary. r Revised.
[1] Excludes Puerto Rico.
[2] Includes portland and masonry cement only.
[3] Includes imported cement shipped by domestic producers only.
[4] Value received, f.o.b. mill, excluding cost of containers.
[5] Quantity shipped plus imports minus exports.
[6] Adjusted to eliminate duplication of imports (clinker and cement) shipped by domestic cement manufacturers.

---

[1] Physical scientist, Division of Nonmetallic Minerals 1970–75. (Now with U.S. Geological Survey, Reston, Va.)

Legislation and Government Programs.—The Housing and Community Development Act of 1974 authorized $8.4 billion to fund over a 3-year period the development of low-income areas of cities, and help home buyers and home builders. In mid-October, the Emergency Home Purchase Assistance Act of 1974 was signed by the President, permitting the Federal Government to pump $7.75 billion into the mortgage market through the Government National Mortgage Association and the Federal Home Loan Mortgage Corp. to stimulate the housing industry. New occupational noise regulations were published on August 7, 1974, in the Federal Register by the Mine Enforcement and Safety Administration and became effective on that date.

On May 28, the Supreme Court denied a petition for certiorari in the case of the Portland Cement Association versus the Environmental Protection Agency (EPA). The U.S. Court of Appeals, District of Columbia Circuit, held that EPA was not required to issue an environmental impact statement in promulgating new source performance standards and that EPA did not have to justify its action in requiring stricter performance from one industry than from another. However, the Court of Appeals ruled that EPA failed to make available to the cement industry sufficient data with respect to test results and procedures upon which the standards were based, and ordered EPA to do so.

The Texas Parks and Wildlife Department ordered Parker Brothers & Co., Inc. one of the major shell dredging firms in the Gulf of Mexico, to cease operation on one tract in the San Antonio Bay because the operation was causing siltation. As a result of the shutdown, two cement plants in the Houston, Tex., area had an immediate 50% reduction in shell feedstocks. Texas shell dredgers may face further problems because the Bay Fishermen and Rockport Conservation Association, Inc., is objecting to renewal of all dredging permits that expired December 31, 1974.

In August EPA gave notice of an air pollution violation to the Ideal Basic Industries, Inc. plant at Baton Rouge, La. In December, the company announced that it would terminate cement production at Baton Rouge on March 31, 1975, and convert the facility to a distribution terminal.

Puerto Rican Cement Co., Inc. signed a consent agreement with the regional office of EPA and the Environmental Quality Board of Puerto Rico that required the company to comply with air pollution control standards through the installation of certain abatement equipment. The consent order protects the company from citizens' suits or abatement actions provided the company follows the terms of the consent order. The 2-year project for the two plants will be financed through a loan from the Government Development Bank of Puerto Rico, to be repaid over 15 years.

The Iowa Air Quality Commission gave Lehigh Portland Cement Co. a final extension until November 1974 to complete installation of dust control equipment but required a 20% curtailment of production from August 15 to November 1.

The Federal Trade Commission (FTC) granted final approval to Holderbank Financiere Glaris Ltd., Switzerland, and St. Lawrence Cement Co., Canada, to transfer portland cement producing assets of the former cement division of BASF Wyandotte Corp. to Wyandotte Cement, Inc., Detroit, Mich. In 1974, Lehigh Portland Cement Co. completed final divestiture required by an FTC consent order by disposing of 6 of its 13 ready-mix concrete plants in Florida. OKC Corp. was seeking to dispose of its investment in OKC Dredging, Inc., formerly Jahncke Service, under terms of an order from FTC. OKC Dredging disposed of its ready-mixed concrete and building materials division. In August, FTC filed a complaint against Gifford-Hill & Co., Inc., seeking divestiture of certain of the company's interests in Georgia and the Carolinas; namely, ready-mixed concrete, prestressed concrete, concrete block, and aggregate businesses.

In March 1974, Centex Corp. settled two of three lawsuits that had been filed against Nevada Cement Co. as a result of dust emissions from the cement plant for a period of time prior to April 1, 1971.

DOMESTIC PRODUCTION

During 1974, 1 State agency and 58 companies operated 182 plants in 41 States and Puerto Rico, manufacturing 1 or more kinds of hydraulic cement.

PORTLAND CEMENT

Manufacturers in the United States and Puerto Rico produced 77,978,000 tons of clinker and imported 1,829,000 tons of foreign clinker to grind 79,486,000 tons of portland cement. Domestic producers shipped 79,482,000 tons of portland cement, which included 1,617,000 tons of imported cement. Stocks at mills, depleted by record shipments in 1973, increased 1.9 million tons. In addition to imported cement shipped by domestic manufacturers, 1.6 million tons of portland cement was imported and shipped or used by others not producing cement in the United States and Puerto Rico.

r Revised.

[1] Includes Puerto Rico.

[2] Includes data for eight white cement facilities: Texas (three); Pennsylvania (two); one each in California, Florida, and Wisconsin, and for grinding plants (seven in 1973; eight in 1974): Two each in Michigan, Pennsylvania, and one each in Florida (1974) and Virginia. Data for the Superior, Wisc., plant are included with Michigan.

[3] Includes cement produced from imported clinker (1973, 2,673; 1974, 1,904).

[4] Grinding capacity based on fineness necessary to grind Types I and II cement, making allowance for downtime required for maintenance.

[5] Includes imported cement. Source of imports withheld to avoid disclosing individual company confidential data.

[6] Data do not add to total shown because of independent rounding.

Thirty-one companies had multiplant operations ranging in number from 2 to 14 plants. Nevertheless, no single company accounted for more than 7.6% of the total clinker production capacity. The 5 largest producers comprised 27.2% of total clinker production capacity, the 10 largest accounted for 47.2%, and the 20 largest had 72.7%. The 10 largest companies in terms of clinker production capacity were Ideal Basic Industries, Inc.; General Portland, Inc.; Martin Marietta Cement; Universal Atlas Cement Div. of United States Steel Corp.; Lone Star Industries, Inc. (including Citadel Cement Corp., a joint venture); Amcord, Inc.; Marquette Cement Manufacturing Co.; Kaiser Cement & Gypsum Corp.; Medusa Cement Co.; and National Gypsum Co. The largest individual plant was at Alpena, Mich., operated by Huron Cement Div. of National Gypsum Co.

Production Capacity.—Three new single-kiln plants (one wet process; two dry process with suspension preheaters) with a combined annual capacity of 1.3 million tons were brought into production early in the year. An additional 9 new kilns started operating at existing plants during the year, while a total of 18 old kilns were permanently removed from service, leaving a net annual capacity increase of about 3 million tons for plant expansions completed. Of the 12 new kilns installed, 7 were wet process and 5 were dry process with suspension preheaters.

At yearend 466 kilns were being operated by 51 companies and a State-owned company in South Dakota at 168 plants in 41 States and Puerto Rico with an estimated 24-hour daily clinker production capacity of 292,700 tons. An average of 55 days' downtime was reported for kiln maintenance and replacing refractory brick. Based on 310 days of operation, the apparent annual clinker production capacity of the industry was 90.9 million tons. However, because of unusually high downtime during the year, the estimated effective annual capacity was 96 million tons, based on 330 working days.

In addition to 168 clinker-producing plants, including 7 white cement facilities, 12 plants operated grinding mills only on imported, purchased, or interplant transfers of clinker. Four of the grinding plants produced only masonry cement, one ground both portland and masonry cements, and seven ground portland cement only. Based on the fineness necessary to grind Types I and II cements and making allowances for downtime required for maintenance, the cement industry in the United States and Puerto Rico had an estimated grinding capacity of 105 million tons of cement annually.

Clinker was produced by wet-process kilns at 100 plants, and by dry-process kilns at 63 plants; 5 plants had both processes in operation. Dry-process kilns with preheaters were becoming increasingly important because of lower fuel consumption. By yearend, 38 kilns equipped with preheaters were in production as follows: 24 suspension preheaters operating at 8 dry process plants and 2 at plants employing both processes; 8 traveling grate preheaters operating at 5 plants; and 7 Grudex preheaters operating on 10 kilns at 2 plants.

With the closing of the white cement facilities at Tampa, Fla., seven white facilities were in operation in the United States. Six of these were operated adjacent to gray cement plants. Table 6 shows the daily clinker production capacities of cement plants in the United States and Puerto Rico, grouped according to relative size.

[3] Total number in operation at plants.

Capacity Changes.—Three new plants were completed in 1974: Two at new locations and one at an old plant site. In April, Gifford-Hill & Co., Inc., started operating its new $25 million plant at Harleyville, S. C. The 15-foot-diameter by 220-foot-long dry-process kiln is equipped with a four-stage suspension preheater having an annual clinker production capacity of 564,000 tons. Full capacity was expected by February 1975. A double drying process was also installed using a Hazemag crusher-dryer followed by a 15- by 125-foot-rotary dryer. Other major equipment included three 2,500-horsepower ball mills, 12 feet in diameter by 32 feet long; one raw-grinding mill, and two finish-grinding mills. United Cement Co., subsidiary of Texas Industries, Inc., completed its new plant at Artesia, Miss., in late January. The 14-foot-diameter by 500-foot-long wet process kiln has an annual capacity of 376,000 tons. In March, Illinois Cement Co., a joint venture of Centex Corp., started operating a new plant at La Salle, Ill., on an old plant site, formerly owned by Alpha Portland Cement Co. The 13.5-foot-diameter by 190-foot-long dry-process kiln equipped with a four-stage suspension preheater has an annual capacity of 376,000 tons. A Loesche roller mill was installed to grind the raw material, and a 2,000-horsepower, 11-foot-diameter by 34-foot-long ball mill was installed for finish grinding.

During the year, 10 major expansions were completed. Santee Portland Cement Corp. added a new 18-foot-diameter by 580-foot-long wet-process kiln at its Holly Hill, S.C., plant, increasing annual clinker production capacity by 726,000 tons to a total of 1,071,000 tons in early 1974. In the spring, Giant Portland Cement Co. completed installation of a 12.5-foot/11.25-foot/13-foot-diameter by 425-foot-long wet-process kiln, a 10- by 32-foot raw mill, and a 12- by 32-foot finish-grinding mill at Harleyville, S.C. Subsequently, one old kiln was permanently shut down, and the new annual production capacity of the plant became 855,000 tons. In May, three old short wet-process kilns were replaced at Clinchfield, Ga., by Medusa Cement Co. with a new 15-foot-diameter by 220-foot-long dry-process kiln equipped with a four-stage suspension preheater. Annual clinker production capacity was increased from 415,000 tons to 790,000 tons.

Ideal Basic Industries, Inc., started up its $25 million addition at Portland, Colo., in August. The 14-foot/16.5-foot-diameter by 500-foot-long wet-process kiln increased annual clinker production capacity by 470,000 tons to 885,000 tons. Other major equipment installed included three 11- by 34-foot, 2,000-horsepower mills (one raw grinding and two finish grinding), a completely computerized control room, and online X-ray analysis. San Juan Cement Co., Inc., began production in October with a new 13-foot/15-foot-diameter by 523-foot-long wet-process kiln, increasing annual clinker production capacity at its Dorado, Puerto Rico, plant by 376,000 tons to 840,000 tons. An 11- by 38-foot, 2,000-horsepower, raw-grinding mill and a 13- by 42-foot finish-grinding mill were installed, and the kiln was equipped with a planetary clinker cooler. Diamond-Kosmos Cement Division of The Flintkote Co. completed a $25 million modernization and expansion project at its Kosmosdale, Ky., plant in December. A 15-foot-diameter by 220-foot-long dry-process kiln equipped with a suspension preheater increased the annual capacity by 245,000 tons to 658,000 tons.

In late 1974, Southwestern Portland Cement Co. increased the annual capacity of its Fairborn, Ohio, plant by 70,000 tons to 620,000 tons at a cost of $12.5 million. A new 15-foot-diameter by 220-foot-long dry-process kiln equipped with a four-stage suspension preheater and a Loesche roller mill were installed near the raw materials deposit 5 miles from the old plant. Clinker is shipped by rail to the old finish-grinding mills. The two oldest kilns will be permanently retired in 1975, and one older kiln will be placed on standby when needed.

Louisiana Cement Co., Div. of OKC Corp., installed a 12.5-foot/14-foot-diameter by 460-foot-long wet-process kiln at its New Orleans, La., plant, increasing annual production capacity from 320,000 tons to approximately 700,000 tons. New 3,000-horsepower raw- and finish-grinding mills, each 12-feet by 36-feet, were also installed. Kiln modifications at Pryor, Okla., by Oklahoma Cement Co. of OKC Corp., increased annual clinker production capacity from 375,000 tons to 450,000 tons. The two expansions cost about $18 million. Monolith Portland Cement Co. completed installation of a 15.5-foot/17.5-foot-diameter by 520-foot-long wet-process kiln at its plant near Tehachipi, Calif. The new kiln, with an annual capacity of 530,-

000 tons, replaced five old kilns.

In addition to the nine old kilns permanently shut down mentioned above, other companies removed old or obsolete kilns from service. At Humboldt, Kans., The Monarch Cement Co. shut down two obsolete kilns in 1974 with production capacity about equal to that of the new kiln that was completed in 1973. Martin Marietta Cement completed a major rehabilitation of its Buffalo, Iowa, plant in February and shut down two old small kilns with an annual capacity of about 108,000 tons. The remaining annual capacity of the plant is 540,000 tons. In December, General Portland Inc., shut down permanently three small kilns at Tampa, Fla., used to produce white cement. Removal of the white cement facilities reduced the annual capacity of the Tampa plant about 2%. Calaveras Cement Div. of The Flintkote Co., removed two 47-year-old kilns from service at its San Andreas, Calif., plant in January.

Planned Expansions and New Plants.—One new plant and 16 plant modernizations and expansions were under construction and scheduled for completion in 1975. Construction began in early 1974 on a $31 million new plant about 7 miles north of Brooksville, Fla., for Florida Mining and Materials Corp. A 14.5-foot-diameter by 229-foot-long dry-process kiln equipped with a four-stage counterflow suspension preheater will have an annual capacity of 564,000 tons when completed in late 1975. Other equipment includes two 2,500 horsepower finish mills.

Missouri Portland Cement Co. started construction of a new 16-foot/18.7-foot-diameter by 540-foot-long dry-process kiln with a single-stage suspension preheater at its Joppa, Ill., plant to increase the annual capacity by 750,000 tons to 1,314,000 tons. Also the company was installing a 13- by 32.75-foot raw grinding mill and a 16- by 50-foot, 8,000-horsepower grinding unit, reportedly the largest finish mill in the United States. The $28 million expansion was scheduled for completion in late 1975. Citadel Cement Corp. was installing a 16.5-foot-diameter by 190-foot-long modified Lepol-type traveling-grate preheater dry-process kiln at Roanoke, Va., doubling the annual capacity of that plant to 1.2 million tons. Included in the $36 million project are two roller mills for raw grinding and two 13- by 34.5-foot finish mills.

Kaiser Cement & Gypsum Corp. began expansion of its San Antonio, Tex., plant to increase annual clinker production capacity by 335,000 tons to 785,000 tons. The project, costing $11.5 million, includes installation of a 13.5-foot-diameter by 190-foot-long dry-process kiln equipped with a suspension preheater and a roller mill for raw grinding. Under a 15-year contract, 75% of the clinker from the new kiln will be sold to Gulf Coast Portland Cement Co. at Houston, Tex. Universal Atlas Cement Div. of United States Steel Corp., expected to complete modernization and expansion of its Leeds, Ala., plant by yearend 1975. New equipment included a 15-foot-diameter by 220-foot-long dry-process kiln equipped with a four-stage suspension preheater, a Hazemag crusher-dryer, a Loesche roller mill for raw grinding that utilizes an electrostatic precipitator for dust collection, and a 9.5- by 35.8-foot finish-grinding mill. Annual production capacity will be increased by 316,000 tons to 634,000 tons. The company was also modernizing and expanding its Buffington, Ind., gray cement plant facilities by installing a Loesche roller mill for raw grinding and four-stage suspension preheaters on the existing kilns to increase annual capacity by 78,000 tons to 585,000 tons; completion was scheduled for mid-1975.

Northwestern States Portland Cement Co. was installing a 15-foot/13.5-foot-diameter by 500-foot-long dry-process kiln at Mason City, Iowa, to increase annual production capacity by 282,000 tons to 1,032,000 tons. Ash Grove Cement Co. was replacing five old wet-process kilns at Louisville, Nebr., with a new 15.5-foot-diameter by 160-foot-long ACL dry process kiln with a 12- by 80-foot traveling-grate preheater. Annual production capacity will be increased by 236,000 tons when the facility is completed in April 1975. The Whitehall Cement Manufacturing Co. had under construction at its Cementon, Pa., plant, a 12-foot-diameter by 165-foot-long dry-process kiln equipped with a four-stage suspension preheater. Scheduled for completion in May 1975, annual production capacity will be increased by 250,000 tons to 794,000 tons. A 3,500-horsepower finish-grinding mill was expected to be operational in September.

Pennsuco Cement & Aggregates, Inc., subsidiary of Maule Industries, Inc., was installing a third kiln at its plant near Hialeah, Fla. The 19.5-foot/17-foot/18.5-

foot-diameter by 580-foot-long wet-process kiln will increase annual clinker production capacity to 1,128,000 tons when completed by mid-1975. An identical kiln with a capacity of 740,000 tons was planned for 1976.

Martin Marietta Cement in a major modernization and expansion project at Roberta, Ala., was modifying two dry-process kilns by enlarging the diameter of the feed end section to increase the annual capacity of the plant by 150,000 tons to 695,000 tons; completion was scheduled for late 1975. Portland Cement Co. of Utah was installing a new 16-foot-diameter by 300-foot-long wet-process kiln at its plant near Salt Lake City, Utah, to increase annual capacity by 145,000 tons to 383,000 tons. Two old kilns will be removed from service but retained on standby status. New equipment in the modernization and expansion project include a ball mill for raw grinding and a 1,750-horsepower, 11.5- by 17-foot finish-grinding mill.

The Monarch Co. expected to complete construction of its second new 12-foot-diameter by 165-foot-long dry-process kiln equipped with a four-stage suspension preheater in the fall of 1975. After old kilns are removed from service, the annual capacity of the Humboldt, Kans., plant will increase by 140,000 tons to 600,000 tons. A 19-foot-diameter, four-stage counterflow suspension preheater was being added to one of the kilns at Stockerton, Pa., by Hercules Cement Co. When work is completed in 1975, the annual capacity of the plant will be raised by 107,000 tons to 765,000 tons, about a 16% increase. Twelve old kilns were being replaced by two 17-foot/19.5-foot-diameter by 500-foot-long dry-process kilns at Alpena, Mich., by Huron Cement Div. of National Gypsum Co. Annual capacity will remain unchanged at 2.5 million tons when completed. When this phase of the modernization program is completed in September 1975, the plant will have a total of 5 kilns that replaced 22 older kilns. Other plant expansions scheduled for completion in 1975 include Coplay Cement Mfg. Co., increasing annual production capacity by 132,000 tons at Coplay, Pa., and Lone Star Industries, Inc., increasing capacity of its Davenport, Calif., plant by 30,000 tons.

In December, Ideal Basic Industries, Inc., announced intentions to terminate cement production at its Baton Rouge, La., plant on March 31, 1975. The facility will be converted to a distribution terminal.

Plans for six additional plant modernization and expansion programs were announced. These were in various stages of planning and construction with completion scheduled for 1976 or 1977. Citadel Cement Corp. was replacing three old kilns at Demopolis, Ala., with a new dry-process kiln equipped with a suspension preheater, increasing annual capacity by 524,000 tons to 750,000 tons when work is completed in 1976. In a $12.7 million expansion program at Mitchell, Ind., Lehigh Portland Cement Co. was installing a new 11.5-foot/13-foot diameter by 360-foot-long dry-process kiln equipped with a single-stage suspension preheater to increase annual clinker capacity by 250,000 tons to 750,000 tons. Also the company will install a 1,500-horsepower finish-grinding mill with completion of the project scheduled for mid-1976. The South Dakota Cement Commission embarked on a $20 million expansion program to install a 15-foot-diameter by 220-foot-long dry-process kiln equipped with a four-stage suspension preheater. Scheduled for completion by mid-1976, the annual capacity of the Rapid City, S. Dak., plant will be increased by 755,000 tons to 1,032,000 tons. New equipment includes a Loesche roller mill for raw grinding and a 13- by 40-foot finish-grinding mill.

Société des Ciments Vicat, of Grenoble, France, in its first venture in North America, acquired the National Cement Co., Inc. facilities at Ragland, Ala., from the Mead Corp. The National Cement Co., Inc. formerly a division of Woodward Iron Co. plant, has changed ownership five times since it was built in 1908 by Gulf Coast Portland Cement Co. The eminent engineer, L. S. Vicat, a pioneer in the cement industry in the early 1800's, was founder of the French company bearing his name. The new company started a modernization and expansion program to increase annual clinker production capacity from 360,000 tons to 800,000 tons over a 3-year period. Construction was started to erect a four-stage suspension preheater over the existing dry-process kiln. When completed in 1976, the long kiln will be cut nearly in half at the preheater. The new facility incorporates the latest Japanese technology, using auxiliary burners in the preheater for calcining raw materials before entering the kiln to increase output 20% to 30% above that of other suspension preheaters. This is the first installation of its kind in the United States. Subsequently, another finish mill will be added to accommodate grinding the additional clinker.

Monolith Portland Cement Co. planned to install a second wet-process kiln, 15.5-foot/17.5-foot-diameter by 520-foot-long, in 1976, identical to the kiln installed at Monolith, Calif., in 1974; annual capacity increase would be 530,000 tons. Ideal Basic Industries, Inc., was modernizing its Knoxville, Tenn., plant to improve productivity in 1976 by 85,000 tons to its rated annual capacity of 470,000 tons. New equipment to be installed includes a 3,000-horsepower raw-grinding mill to replace three small mills and two 2,000-horsepower finish-grinding mills. Ideal announced plans to build a new plant near Mobile, Ala., with an annual capacity of 1.5 million tons at a cost of $150 million, contingent on certain conditions.

Cement Grinding Facilities.—In addition to the new finish-grinding mills mentioned in the foregoing section, other cement plants increased grinding capacity. Columbia Cement Corp., subsidiary of Filtrol Corp., installed preliminary grinding mills at Zanesville, Ohio, to increase grinding capacity by 10%. Phoenix Cement Co. added a new finish-grinding mill at its Clarkdale, Ariz., plant. Gulf Coast Portland Cement Co. completed construction of a new finish mill that doubled annual grinding capacity to 750,000 tons at its Houston, Tex., plant. Arizona Portland Cement Co. completed its new finish-grinding mill at Rillito, Ariz., to increase annual grinding capacity from 500,000 tons to 1,150,000 tons. Kaiser Cement & Gypsum Corp. made modifications to finish mills at Permanente, Calif., costing $0.55 million and spent another $0.44 million at Cushenburry, Calif., installing a new raw mill to raise the annual capacity of that plant to equal kiln production of 1,015,000 tons. River Cement Co. completed its $6.9 million expansion at Festus, Mo., to bring finish-grinding capacity up to 1.2 million tons, an increase of 28%.

The National Portland Cement Co. of Florida completed its 11- by 34-foot finish-grinding mill at Port Manatec near Bradenton, Fla., with an annual capacity of 282,000 tons. The plant operated on clinker imported from Europe.

Cyprus Hawaiian Cement Corp., subsidiary of Cyprus Mines Corp., was installing a 2,000-horsepower, 11- by 33-foot finish-grinding mill at its plant near Barber's Point, Hawaii. The $6.8 million expansion program to increase annual capacity from 200,000 tons to 275,000 tons was scheduled for completion in early 1975. In 1975, Medusa Cement Co. planned to install a new $3.6 million finish-grinding mill at Clinchfield, Ga., to increase annual grinding capacity from 700,000 tons to 790,000 tons. Marquette Cement Manufacturing Co. announced a $7 million project to modernize finish-grinding mills at its Hagerstown, Md., plant.

In addition to the new National Portland Cement Co. of Florida grinding plant, the following companies operated grinding facilities on imported, purchased, or interplant transfers of clinker: Jefferson Marine Terminal, Detroit, Mich.; Wyandotte Cement, Inc., Wyandotte, Mich.; Lone Star Industries, Inc., Norfolk, Va.; Universal Atlas Cement Div. of United States Steel Corp., Milwaukee, Wisc.; and Allentown Cement Div., National Gypsum Co., West Conshohocken, Pa. G. & W. H. Corson, Inc., produced both portland and masonry cements at its grinding plant in Plymouth Meeting, Pa.

Table 7.—Raw materials used in producing portland cement in the United States[1]

(Thousand short tons)

Raw materials	1973	1974
Calcareous:		
Limestone (includes aragonite)	r 85,699	87,667
Cement rock (includes marl)	26,067	23,417
Oystershell	5,144	4,922

Total	r 138,188	137,227

r Revised.

[1] Includes Puerto Rico.

MASONRY CEMENT

Shipments of masonry cement were 3.4 million tons, down 17% from the record 4.1 million tons shipped in 1973. The unit value increased $3.50 per ton to $32.93, and the total value of shipments was $113 million. By yearend, 114 plants were manufacturing masonry cement. Four plants produced masonry cement exclusively: Cheney Lime & Cement Co., Allgood, Ala.; Martin Marietta Cement, North Birmingham, Ala.; M.J. Grove Lime Div. of The Flintkote Co., Frederick, Md.; and Riverton Corp., Riverton, Va. In some States, masonry cement was not produced because the majority of the masons preferred to purchase portland cement and add clay or lime for plasticity on the job. Despite a decline in sales, masonry cement imports in 1974 were 102,600 tons.

Table 8.—Masonry cement shipped by producers in the United States, by district[1]

(Thousand short tons and thousand dollars)

District	1973			1974		
	Quantity	Value	Average per ton	Quantity	Value	Average per ton

[1] Includes imported cement.
[2] Less than 500 short tons.
[3] Includes 2,997 tons produced from clinker and 1,025 tons produced from cement in 1973; and 2,558 tons produced from clinker, and 844 tons produced from cement in 1974.
[4] Data do not add to total shown because of independent rounding.

ALUMINOUS CEMENT

Aluminous cement, also known as calcium aluminate cement, high-alumina cement, and "Ciment Fondu," is a nonportland hydraulic cement produced at three plants in the United States. Universal Atlas Cement Div. of United States Steel Corp., manufacured calcium aluminate clinker and cement at a facility adjacent to its gray portland cement plant in Buffington, Ind. The Aluminum Co. of America operated kilns and grinding facilities to produce aluminous cement at Bauxite, Ark. Lone Star Lafarge Co., a joint venture between Lone Star Industries and the Lafarge Group, grinds calcium aluminate cement from imported clinker at Norfolk, Va.

SLAG CEMENT

Slag cement has not been manufactured in the United States since 1972. Some shipments of slag cement were made from stocks at mills during 1973, but no slag cement shipments were made in 1974. The last plants to produce slag cement—Martin Marietta Cement at North Birmingham, Ala., and Cheney Lime & Cement Co. at Allgood, Ala.—experienced considerable difficulty obtaining granulated slag from local steel mills and were unable to purchase an adequate supply elsewhere.

ENERGY

Shortages of fossil fuels and sharp price increases for all fuels were of primary concern to cement manufacturers. Imported fuel oil costs quadrupled, compelling many companies to convert to coal as primary fuel, while others were in various stages of planning and installing coal-handling facilities. Some companies acquired coal resources while others made long-term purchase contracts.

Although Lone Star Industries, Inc. was converting the majority of its plants to coal burning, the company continued to drill for natural gas in Oklahoma, Texas, and New Mexico and made plans for drilling another gas well in Colorado.

Marquette Cement Manufacturing Co. acquired coal properties in 1974 in Sequatchie County, Tenn. The company expects to start mining coal from this property in the second half of 1975 to supply two of its cement plants. Medusa Corp. began strip-mining coal and continued to explore for oil and natural gas.

National Cement Co., Inc., acquired its own coal mine and will convert the Ragland, Ala., plant from natural gas to coal as a primary fuel, utilizing fuel oil as a standby fuel. In 1974, United Cement Co. burned coal that was purchased, but the company anticipates that by 1975 it can ship from company-owned coal mines in Tennessee to its plant at Artesia, Miss.

In September, California Portland Cement Co. acquired an existing underground coal mine near Price, Utah. The mine contains high-quality coal with estimated reserves of recoverable coal in excess of 12.5 million tons that are adequate for 25 years of cement production at all three plants. Soldier Creek Coal Co., a subsidiary of the company, will operate the mine, expected to be in production by yearend 1975. The company was installing coal-burning facilities at each of its three plants in California and Arizona at a cost of about $2.2 million for each plant.

Early in 1974, Ideal Basic Industries, Inc., and Rocky Mountain Energy Co., a subsidiary of Union Pacific Corp., formed a joint venture, Stansbury Coal Co., to reopen and expand an underground coal mine near Rock Springs, Wyo. The mine was scheduled to start production in early 1976 with an initial annual capacity of 1.25 million tons, expandable to 1.5 million tons. Most of the mine's production capacity has been committed under long-term sales contracts, in part to five Ideal cement plants and in part to other customers. The company was exploring a coal deposit in Oklahoma and expects by 1978 to supply six of its plants in the Central States and on the Gulf Coast, including the proposed Mobile, Ala., plant. The company estimates the cost to convert an average size plant to burn coal to be about $2 million.

Until 1973 Kaiser Cement & Gypsum Corp. had a noninterruptible contract for the supply of natural gas to its San Antonio, Tex., plant. A regulatory agency in Texas established a system of priorities that superseded the previous contract, and the plant's supply of natural gas from that source was drastically reduced. In 1975 the plant will be converted to use coal for primary fuel at a cost of $1.6 million.

Petroleum coke was becoming an important fuel in the manufacture of cement. General Portland Inc. converted its dry-process plant in California to use petroleum coke as primary fuel; coke is a refinery waste product and a lower cost fuel. The company's Tampa and Miami, Fla., plants were also converted to use petroleum coke as primary fuel.

Dundee Cement Co. was using additives (pozzolan) as one way to conserve energy. High cost of fuel was responsible for an increase in the production of Type IP, portland-pozzolan cement, and Type IS, portland-blast furnace slag cement. Shipments of Type IP and Type IS in 1974 were 672,000 tons, compared with 1,021,000 tons in 1973, 438,000 tons in 1972, and 104,000 tons in 1971.

Table 10.—Clinker produced in the United States, by kind of fuel [1]

Year and fuel	Clinker produced			Fuel consumed

[r] Revised.

[1] Includes grinding plants and white cement facilities.

[2] Includes Puerto Rico.

[3] Includes data for grinding plants, seven in 1973; eight in 1974.

TRANSPORTATION

Trucks continued to haul most of the cement delivered to customers in the United States. However, railroads and barges transported most cement shipments from manufacturing plants to distribution terminals. Trucks hauled 84% of the total cement shipments to customers, railroads moved 14%, and 2% was transported by water. However, waterborne transportation was becoming increasingly important. Recent studies on comparative efficiencies of various freight modes indicated that 1 gallon of fuel would move 300 ton-miles of freight by water, compared with 180 ton-miles by rail and 50 ton-miles by truck. Other studies expressed the average energy intensiveness of transportation modes in terms of British thermal units (Btu) of energy required to move freight on a ton-mile basis as follows: Inland waterway carriers, 415 Btu per ton-mile; railroads, 750 Btu per ton-mile; pipelines, 1,850 Btu per ton-mile; trucks, 2,400 Btu per ton-mile; and air freight, 63,000 Btu per ton-mile.

Individual long-haul waterway carriers reported fuel requirements considerably below averages; for example, deep-draft vessels such as the iron ore carrier *Charles F. Wilson*, operating on the Great Lakes, consume only 96 Btu per ton-mile. Most recent statistics showed that the cost of shipping by barge was 0.378 cent per ton-mile compared with 1.62 cents per ton-mile by rail, 8.25 cents per ton-mile by truck, and 23.31 per ton-mile by air.

A trend, started in 1972 by many companies to reduce market areas by selective marketing has reduced transportation costs from earlier costs of about 25% to about 10% of the delivered price.

In mid-1974, California Portland Cement Co. acquired the cement distribution terminal at the Port of Redwood City, Calif., from Ideal Basic Industries, Inc. The company was supplying the facility with cement shipped by rail from its Mojave plant. Atlantic Cement Co., Inc. expanded storage capacity at its distribution terminal at Jacksonville, Fla., from 7,500 tons to 38,000 tons. Columbia Cement Corp. enlarged its distribution terminal at Portland, Oreg.

A nonmanufacturer of cement, Rinker Materials Corp. of West Palm Beach, Fla., added two silos to increase storage capacity by 16,000 tons to 40,000 tons and completed bagging facilities at its terminal at Port Everglades, Fla., in April. The company plans to build a new cement terminal at Cape Canaveral, Fla., with storage capacity of 40,000 tons; completion was scheduled for July 1975.

Kaiser Cement & Gypsum Corp. installed a new distribution facility at Phoenix, Ariz., with 400 tons of storage. The company also increased storage capacity from 500 tons to 1,500 tons at its distribution terminal at Lihue on the island of Kauai, Hawaii. In late 1974, Kaiser completed a new $1.4 million distribution facility at Agana, Guam, increasing storage capacity by 800 tons to 9,300 tons. Cement purchased by Kaiser from Asian manufacturers was sold to customers in the Far East, utilizing two company-owned bulk ships, MV *Orient Carrier*—6,000 deadweight tons (dwt) and MV *Taipan*—5,000 dwt.

Missouri Portland Cement Co. had 9 barges under construction to be added to its fleet of 36 company-owned rock and cement barges. The company reported fuel savings up to 80% using water transportation, compared with costs using truck and rail.

Arkansas Cement Corp. was constructing a cement distribution terminal at Alexandria, La. Completion was scheduled for early 1975. Dundee Cement Co. was moving a large metal hopper silo from Monroe, Mich., to its distribution terminal at Lemont, Ill. When the $400,000 project is completed in 1975, the total storage capacity will be increased to 6,500 tons. Cement is transported by barge to the facility.

Single-commodity trains ("commoditrain"), inaugurated by the Chicago and North Western Railroad in 1972, continued to transport cement from two manufacturers in Mason City, Iowa, to distribution terminals in Burnsville, Minn. Trains carrying a minimum load of 2,000 tons make five 275-mile round trips per week during the construction season.

General Cement Co. (AGET) of Greece replaced its 4,800-dwt cement bulk carrier, *Tsimentarches*, which was hit and destroyed in Latakia harbor during 1973 hostilities in the Middle East, with a newly built fully automated 4,200-dwt carrier, *Perseus*, from Norway. In January, its new 6,500-dwt bulk carrier, *Theseus*, was launched in a Japanese shipyard.

Table 13.—Shipments of portland cement from mills in the United States, in bulk and in containers, by type of carrier [1]
(Thousand short tons)

r Revised.
[1] Includes Puerto Rico.
[2] Includes waterproof cement.

CONSUMPTION AND USES

Shipments of cement into various States are considered to be an index of consumption. Portland cement consumption decreased 8% below the 1973 record shipments. Consumption shown in table 14 decreased in all but 12 States and shipping districts. The largest decrease was in Florida with 866,000 tons; followed by Southern California, 828,000 tons; Illinois, 556,000 tons; Ohio, 510,000 tons; and Texas, 462,000 tons. The largest increase was in the District of Columbia with 100,000 tons, followed by Washington with 63,000 tons, and Oklahoma with 55,000 tons. Consumption in northern California and Utah was virtually unchanged from shipments in 1974.

Producers of ready-mix concrete were the primary customers for portland cement, receiving 65.8% of total shipments. Concrete product manufacturers used 14.5% of the cement to make concrete blocks, concrete pipes, precast-prestressed concrete, and other concrete products. Direct shipments to highway contractors amounted to 7.5% of the total cement consumed during the year. Building materials dealers received 7.5% of the shipments, other contractors received 3.0%, Federal, State and other government agencies purchased 0.4%, and 1.3% went for miscellaneous uses.

New housing unit starts in 1974 were down 34% below those in 1973; nevertheless, because of inflation, the value of new construction put in place was down only one half percent. Private construction value decreased 6% below the 1973 record, while value of public construction increased 18%. Residential construction value was down 23% for single-unit and multi-unit housing combined. Value of total private nonresidential buildings was up 8%, led by industrial construction, 24%; farm (other than residential), 25%; office buildings, 4%; other commercial buildings, 3%; hospitals and institutional buildings, 5%; and religious construction, 16%. Private educational building declined 20%. Private public utilities construction value was up 11%, led by electric power construction, 11%; and telephone, 8%. Total value of public construction advanced 15%, comprising the following increases: Sewer systems, 37%; water supply facilities, 29%; conservation and development, 20%; highways, 15%; hospitals, 24%; industrial, 26%; educational, 10%; and other public buildings, 23%.

PRICES

The average mill value[3] of portland cement (all types) was $26.52 per ton in 1974, an increase of $4.64 per ton. The mill values ranged from lows of $23.80 in Michigan and $24.20 in Kansas to highs of $29.33 in Florida, $33.69 in Hawaii, and $37.36 in Puerto Rico.

The Bureau of Mines collects mill value for cement shipments but does not canvass cement prices. However, according to

---

[3] Mill value is the actual value of sales to customers, f.o.b. plant, less all discounts and allowances, less all freight charges to customers, less all freight charges from producing plant to distribution terminal, if any; less total cost of operating terminal, if any; less cost of paper bags and pallets.

Engineering News-Record, December bulkmill prices ranged from $26.60 in Hagerstown, Md., to $57.60 in Waianae, Hawaii. Bagged cement prices were $6 to $10 per ton higher than bulk prices. All prices were subject to cash discounts. Base prices for portland cement in carload lots f.o.b. were reported monthly in Engineering News-Record for 20 cities in the United States. The December 1974 average for bulk cement was $33.45 per ton, compared with $26.76 in December 1973. In the 20-city survey, bulk prices ranged from a low of $30.40 per ton in Pittsburgh, Pa., to highs of $37.40 per ton in Boston, Mass., and $37.20 per ton in San Francisco, Calif. Masonry cement averaged $50.70 per ton in December 1974 and ranged from $43.14 per ton in Birmingham, Ala., to $65.71 per ton in Kansas City, Kans.

The Department of Consumer Affairs, in Puerto Rico, which attained cabinet status in 1973, regulates consumer prices. In January, an emergency price increase of 25 cents was granted, raising the price of a bag of cement at the manufacturers level to $1.85, followed by another 7-cent increase in April. On July 18, 1974, the Department of Consumer Affairs approved a new pricing structure for cement in Puerto Rico that creates a price differential between bagged and bulk cement and granted price increases of 26.05 cents for bagged cement and 0.0005 cent for bulk cement. Approximately 47% of the cement is sold in bags. The new price structure also allows automatic "pass throughs" for increases in certain cost items such as fuel, power, local transportation, gypsum, and property taxes. These costs account for about 60% of the cost of producing cement. By yearend, the price of a bag of cement was $2.239 bagged and $1.979 bulk equivalent. Beginning January 1, 1975, a new price formula will provide for a reasonable return on capital invested in the production of cement, with an objective of 12% return.

Skyrocketing fuel prices and inflation rates, much higher than in the United States, were responsible for substantial increases in foreign cement prices. A sampling of price increases above 1973 prices for selected countries follows: Kingston, Jamaica, 81%; Beirut, Lebanon, 77%; Tel Aviv, Israel, 77%; Singapore, 73%; Milan, Italy, 72%; Athens, Greece, 62%; Ankara, Turkey, 52%; Buenos Aires, Argentina, 42%; Tehran, Iran, 37%; Stockholm, Sweden, 36%; Tokyo, Japan, 26%; Sidney, Australia, 25%; Paris, France, 22%; Rio de Janeiro, Brazil, 18%; Brussels, Belgium, 17%; New Delhi, India, 17%; and Panama, 16%. While the bag price was unchanged in Lima, Peru, the size of the sack of cement was reduced from 93 pounds to 26 pounds.

Table 17.—Average mill value in bulk of cement in the United States[1]
(Per short ton)

Year	Portland cement	Prepared masonry cement[2]	All classes of cement
1970	$17.69	$22.68	$17.88
1971	18.74	25.28	19.01
1972	20.31	26.52	20.59
1973	21.88	29.43	[r] 22.23
1974	26.52	32.93	26.79

[r] Revised.
[1] Includes Puerto Rico.
[2] Masonry cement made at cement plants only.

FOREIGN TRADE

Although hydraulic cement exported from the United States decreased 11% in quantity, the value increased 65%. In relative importance, cement exports amounted to less than 0.4% of the quantity and 0.8% of the value of total domestic shipments. Six countries—Canada, the Dominican Republic, Mexico, the Netherlands Antilles, the Leeward and Windward Islands, and Jamaica—received 88% of the 289,800 tons of cement valued at $14,860,000 exported to 82 countries.

Portland cement and clinker imported from 16 countries, for consumption in the United States and Puerto Rico, decreased 14% in quantity and 2% in value from the record 1973 imports. Nevertheless, despite an 8% decrease in domestic production caused by a general economic recession, imports comprised 7% of total domestic cement shipments. Nearly 60% of the imports entered at Customs Districts in two States—Florida (37.5%) and New York (22.4%).

Canada continued to be the leading exporter, supplying 39% of the imported cement and clinker, followed by the Bahamas with 14%; Norway and the United Kingdom, 12% each; France, Spain, and West Germany, 5% each; and Mexico, 4%.

Clinker comprised 32% of the total imports in 1974, compared with 41% in 1973, 34% in 1972, 24% in 1971, and 15% in 1970. Four plants operated exclusively on imported clinker—two in Michigan and one each in Florida and Virginia. An additional 15 plants supplement their cement production by grinding imported clinker.

While imports comprised 7% of domestic shipments, cumulative total imports of 5.7 million tons exceeded the quantity of cement manufactured in all individual producing States with the exception of California, Pennsylvania, and Texas.

The rate of duty on white, nonstaining portland cement was 1.0 cent per hundredweight including the weight of container; other hydraulic cement and clinker were duty free, as granted in the final stage of the Kennedy round of trade negotiations under the General Agreement on Tariffs and Trade (GATT). However, the statutory import duty from countries that do not have most-favored-nation status was 8 cents per hundredweight for white, nonstaining portland cement and 6 cents per hundredweight for other hydraulic cement and clinker.

World trade of cement and clinker was about 30 million tons, out of 780 million tons comprising total world shipments.

WORLD REVIEW

In 1974, about 1,700 clinker-producing cement plants in some 140 countries were operating, with an estimated total annual capacity of 900 million tons. In addition, more than 2,800 very small plants were reportedly operating in many communes and municipalities in the People's Republic of China, accounting for more than 50% of that country's estimated 35-million-ton capacity. Many new plants, plant expansions, and plant modernizations were under construction or in various stages of planning and financing throughout the world.

The world cement situation continued to be a dichotomy of chronic shortage in many countries, particularly in Asia, Latin America and Africa, while considerable surplus existed in North America, Europe and some countries in the Far East. The serious economic recession, high inflation, high interest rates, and sharply rising fuel costs experienced in the United States affected the economies of most other countries and specifically their construction industries.

A construction slump in 19 European countries belonging to the European Cement Association (CEMBUREAU) was responsible for a 2.6% decrease in cement production in 1974, the first decline since World War II. Many kilns and some plants were taken out of production because of the depressed market. Nevertheless, during the year, seven new plants with a combined annual capacity of 3.5 million tons started operations in member countries. An additional 19 new kilns went into production with a combined annual capacity of 12.2 million tons. Six new plants and 15 plant expansions were under construction that will increase annual clinker production capacity by 14.3 million tons when completed in 1975.

Although cement price increases ranged from 7% to 105% in member countries, cement prices rose an average of 30% following sharp increases in fuel and power costs combined with the inflationary trend of all manufacturing cost items.

Algeria.—Société National des Materiaux de Construction (S.N.M.C.) was expanding production capacity at its Zahana plant about 22 miles southeast of Oran with a new 18-foot-diameter by 275-foot-long-dry-process kiln equipped with a four-stage suspension preheater. Annual clinker production capacity will be increased by 1.1 million tons when completed in early 1977. The company announced plans for construction of a new plant at El Asnam about 99 miles southwest of Algiers. The dry-process kiln equipped with a suspension preheater will have an annual capacity of 1.1 million tons. Completion was expected in early 1979. S.N.M.C. was constructing a 14.5-foot-diameter by 230-foot-long kiln equipped with a four-stage suspension preheater at its Hadjar Soud plant. The new addition will have an annual capacity of 550,000 tons, the same as the first unit.

Barbados.—The Governments of Barbados and Guyana proposed to build a cement plant in Barbados with an initial capacity of 270,000 tons. Clinker would be shipped to the state-owned Guyana Bauxite Co. Ltd. (Guyban) for finish grinding. Completion was scheduled for May 1976.

Belgium.—In October, S.A. Cimenteries C.B.R. Cementliedryuen U.V. started operating a new slag-cement plant with an annual capacity of 550,000 tons near Gent. The company, in a joint venture with Eerste Nederlandse Cement Industrie, was constructing a new kiln at its Lixhe plant with an annual capacity of 1.1 million tons. Completion was expected in 1976. Ciments d'Obourg S.A. was installing a 23.5-foot/20.8-foot-diameter by 745-foot-long wet-process kiln with production capacity of 1.1 million tons at its Obourg plant. The new kiln, one of the largest in the world, was scheduled for production by mid-1975.

Bhutan.—The Bhutan Government contracted for a cement plant with an annual capacity of 110,000 tons to be constructed at Pagli. Completion was expected in 1978.

Brazil.—Cimento Tupi, S.A., was constructing a new plant, with a 15-foot-diameter by 220-foot-long kiln with a suspension preheater, at Pedro de Sino in Minas Gerais that was scheduled for completion in late 1975. Ube Industries, Ltd., and Nissho-Iwai Co. of Japan, in a joint venture with Brazilian firms, formed the company Industrias de Cimento Portland Cantagalo S.A. to build a cement plant with a daily capacity of 2,640 tons at Cantagalo near Rio de Janeiro. Completion was scheduled for late 1975. Cia. de Cimento Nacional de Minas S.A. (CIMINAS) started operation of its Pedro Leopoldo plant, with a dry-process kiln equipped with a four-stage suspension preheater in December 1974. Annual capacity of the plant, located near Belo Horizonte, Minas Gerais, was 990,000 tons.

Bulgaria.—The Bulgarian Government was seeking bids to construct a cement plant with an annual capacity of 2 million tons.

Burma.—Plans were made to establish a new $25 million cement plant with an annual capacity of 240,000 tons at Kyaukse about 20 miles south of Mandalay. Construction will be implemented with assistance from the People's Republic of China. When completed in 1978, Burma's production capacity will be 864,000 tons.

Canada.—Canada Cement LaFarge Ltd. installed a new kiln at its St. Constant, Quebec plant, which doubled the annual capacity to 1 million tons at a cost of $25 million. After the company completed its new dry-process (single-stage preheater) plant with production capacity of 1.1 million tons at Bath, Ontario, in September 1973, the old Bellville, Ontario, plant was phased out. The company was replacing two old kilns at its Exshaus, Alberta, plant with a new kiln with a production capacity of 500,000 tons that will increase the plant capacity by 200,000 tons when completed in 1975 at a cost of $30 million. Also the company was modernizing its Havelock, New Brunswick, plant to increase annual capacity by 100,000 tons. Canada Cement LaFarge Ltd. announced a $13 million modernization of its Montreal East plant, converting from a wet to a dry process. Completion was scheduled for late 1976.

Lake Ontario Cement Ltd., in the second phase of a major expansion of its Picton, Ontario, plant, was installing a new dry-process kiln equipped with a four-stage suspension preheater, having an annual capacity of 850,000 tons. When it is completed in late 1975, older kilns will be placed on standby. St. Mary's Cement Company Ltd. completed installation of a new kiln at its Bowmanville plant that increased annual capacity to 700,000 tons. The company planned to double the capacity of its St. Marys, Ontario, plant by late 1976. The expansion will include a new kiln with an annual capacity of 500,000 tons that was estimated to cost $30 million.

Genstar Ltd. announced plans to build a new $60 million plant on the British Columbia mainland with production capacity of 750,000 tons. Haida Cement Co. Ltd., a newly formed company, planned to build a plant at New Westminster, British Columbia, with completion scheduled for late 1975. Equipment will include a dry-process kiln equipped with a suspension preheater having an annual capacity of 330,000 tons. Houg Cement Ltd. planned to build a small cement plant near Clyde, about 40 miles northeast of Edmonton, Alberta.

Central African Republic.—Plans were revised to erect the clinker-grinding plant at Bangui, with an annual capacity of 55,000 tons.

China, People's Republic of.—About 2,800 small cement plants were reportedly operating in 80% of China's counties, accounting for more than 50% of the national cement output. Quality of the cement was improved. Following is a brief summary of small cement plants in some provinces and autonomous regions. In Honan Province more than 140 small plants have produced about 6.6 million tons of cement since 1970. Sinkiang had 37 small plants, accounting for 66% of the Province's cement output. Sinkiang's first small plant has an annual capacity of 22,000 tons. Kwangsi had 112 small cement works established since 1966 in 80 counties or cities. Tsinghai Province had 17 plants, with a yearly output of 55,000 tons. Kansu Province had more than 80 small cement plants, accounting for one-third of the Province's total output. The Wuwei County plant achieved an annual output of 7,500 tons. Seventy-one counties in Slensi Province operated small works, accounting for 41% of the Province's total cement output. The Tachai cement plant in the Siyang district of Shansi Province increased annual capacity from 7,700 tons to 22,000 tons by modification of the vertical kilns. Potash was recovered for fertilizer from the kiln dust.

The Liku plant in the Hsinhsiang region of Honan Province increased daily output to more than 330 tons and reduced the cost from 88 yuan to 31 yuan per ton.[3]

---

[3] 1 yuan=about $2.2.

The Maanshan municipal cement plant in Anhwei Province increased annual output to 33,000 tons of grades 400 and 500 cement. Puyi-Miao Autonomous Chou in south Kweichow has eight cement works. Tungtuchen, capital of Haman Li Miao Autonomous Chou, is a new city that recently established a cement works with an annual capacity of 11,000 tons.

China has more than 50 large plants, some with capacities exceeding 1 million tons. The capacity of the country's cement industry was estimated to be more than 33 million tons.

Colombia.—Cementos Boyacá S.A. was installing a new cement mill, 13.8 feet in diameter by 44.5 feet long, and slag-drying equipment that will enable the production of slag cement at its Nobsa plant. The new 4,500-horsepower grinding mill with an hourly capacity of 98 tons was expected to be in operation during the second half of 1975. Compañía Colombiana de Clinker S.A., a newly organized company, was building a plant near Cartagena. Equipment will include two wet-process kilns with a combined daily capacity of 2,200 tons.

Costa Rica.—In September, Industria Nacional de Cemento S.A. completed the conversion of an idle wet-process kiln to a dry-process kiln equipped with a two-stage suspension preheater. This increased the annual capacity of the Cartago plant by 165,000 tons to 495,000 tons.

Cyprus.—Cyprus Cement Co., Ltd., was installing a new kiln to increase the capacity of its Limassol plant by 275,000 tons to 385,000 tons.

Denmark.—A new kiln was installed at the Rordal plant by A/S Aalborg Portland Cement-Fabrik (APCF). Production capacity was increased by 275,000 tons per year. On January 1, 1975, APCF will become the country's sole cement producer when it acquires Dansk Andels Cement Fabric A.m.b.a.

Dominican Republic.—Cementos Nacionales S.A. was constructing a new cement plant near the port of San Pedro de Macoris about 43 miles east of Santo Domingo. The dry-process kiln, 15 feet in diameter by 220 feet long and equipped with a suspension preheater, has an annual capacity of 560,000 tons and was scheduled for completion in September 1975.

Ecuador.—La Cemento Nacional C.A. was planning expansion of annual capacity at its San Eduardo plant near Guayaquil by 550,000 tons. Equipment includes a 14.5-foot-diameter by 204-foot-long dry-process kiln equipped with a suspension preheater and a 13-foot by 41-foot, 4,000-horsepower finish-grinding mill.

Egypt.—Ste. Egyptienne de Ciment Portland Tourah was planning to expand the annual capacity of its Tourah plant near Cairo from 1.4 to 2.1 million tons, with an addition of a dry-process kiln.

Finland.—Paraisten Kalkkivuori Oy was replacing two old kilns with a new dry-process kiln at its Pargas plant, 22 miles south of Turku. When completed in January 1975, the capacity will be increased by 500,000 tons. Lohjan Kalkkitehdas Oy was changing its plant at Virkkala with an annual capacity of 1.1 million tons from wet to dry process.

France.—S.A. des Ciments Portland de Lorraine installed a new kiln at its Heming plant with an annual capacity of 495,000 tons. Ciments d'Origny Desvroise completed construction of a kiln with an annual capacity of 545,000 tons at its Lumbres plant. Société des Ciments Français replaced an old kiln with a new kiln and increased production capacity at its Couvrot plant by 1.08 million tons. S.A. des Ciments de Dannes et Lavocat had a new kiln under construction at the Dannes plant to replace two old kilns; this kiln should increase annual capacity by 154,000 tons when completed in 1975. Ciments LaFarge was constructing two kilns with combined capacity of 110,000 tons at Dunkerque to produce "Fondue" aluminous cement; completion was scheduled for 1975.

Germany, West.—Six new kilns, which increased the country's annual capacity by about 2.2 million tons, were installed during the year by Anneliese Portland Cement and Wasser Kalkwerke A.G. at Ennigerloh (1.1 million tons); Buderus'sche Eisenwerke Wetzlav at Wetzlav (1.1 million tons); Portland-Zementwerke Heidelberg A.G. at Burg-Lengenfeld (715,000 ton); Märker Zementwerk G.m.b.H. at Harburg (1.1 million tons); Portland-Zementwerke Obergimpern G.m.b.H. at Obergimpern (550,000 tons); and Sudbayer Portlandzementwerk Gebr. Weisbock & Co., G.m.b.H., at Rohrdorf (1.1 million tons). At least 21 kilns were replaced or removed from production in the country during the year. Nordcement A.G. ceased clinker production at its "Siegfried" plant, Salzderhelden, at yearend, removing 418,000 tons of annual capacity.

Greece.—In February, Chalkis Cement Co. S.A. started clinker production from its new dry-process kiln equipped with a suspension preheater. Annual capacity of the plant at Mikro Vathi, Avlis, was increased by 1.1 million tons to 1.87 million tons. An identical kiln under construction was scheduled for completion by yearend 1975 to bring the plant capacity to a total of 2.97 million tons. In July, ground was broken for General Cement Company's new plant at Methana in eastern Peloponnesus, with annual clinker production capacity of 1.5 million tons; completion was scheduled for yearend 1975. However, construction was suspended because some Government officials considered the plant harmful from an environmental and tourist standpoint. Halyps Cement Co. was installing a new kiln to replace three obsolete kilns at its Aspropyrogo plant in Attica. When completed, annual capacity will be increased by 660,000 tons to 1 million tons. Titan Cement Co. S.A. was constructing a new plant at Kamaris, Bestea, with an annual capacity of 1.1 million tons. Completion was scheduled for late 1975. M.A. Karageorgis S.A. was building a new plant at Messinia, South Peloponnesus, with an annual capacity of 1.1 million tons. The Government has approved the following investments: A $45 million plant in the Arcadia area with a capacity of 1.1 million tons; a $38.5 million plant in Laconia or Arcadia, Peloponnesus, with a capacity of 1 million tons; and an $18.2 million plant in the Preveza area with a capacity of 310,000 tons.

Guatemala.—Cementos Novella S.A. completed its new plant at San Miguel with a 13.6-foot by 195-foot-long dry-process kiln equipped with a four-stage preheater.

Hungary.—Cement es Meszmuvek Vezeriyazgatosaga was replacing five old shaft kilns with two 15-foot-diameter by 263-foot-long dry-process kilns equipped with suspension preheaters at its Hejocsaba plant near Miskolc, completion was scheduled for 1975. Each kiln has a daily capacity of 2,200 tons. Three finish-grinding mills are each 14.5 feet in diameter by 49 feet long with dual drive by two 2,100-kilowatt motors. When completed, it will be Hungary's largest cement works, with an annual capacity of 1.6 million tons of portland cement and portland-blast furnace slag cement. Construction was started at the Balapatfalva plant to increase capacity to 1.2 million tons when completed in 1978.

Iceland.—Although clinker production capacity remained unchanged at 110,000 tons per year, grinding capacity was increased by Sementsverksmidja Rikisins at its Akranes plant to 143,000 tons with the installation of a new mill.

Indonesia.—At least eight new plants and plant expansions including three Governments projects, with combined capacity of 4.4 million tons, were in various stages of planning and construction. P.T. Semen Cibinong experienced delays in construction of its new plant with production capacity of 628,000 tons at Cibinong, West Java, and completion was expected about October 1975. The delays and rapid inflation raised the cost of the plant from $35 million to $41 million. The company plans to increase the annual capacity of this plant to 1.1 million tons by adding a 15-foot-diameter by 220-foot-long dry-process kiln with a preheater. Estimated cost of the expansion was an additional $47.5 million, and completion was scheduled in 1977. P.T. Semen, Indonesia, was constructing a large plant near the site of the Cibinong plant. A joint venture between P.T. Gunung Ngadeg Jaya and Onoda Cement Co. Ltd. of Japan had an application awaiting Government approval to build a cement plant with an annual capacity of 550,000 tons in Cilacap, Central Java, costing $49.5 million. P.T. Semen, Baturaja, was installing a kiln at a new clinker manufacturing plant in Baturaja, South Sumatra, with an annual capacity of 550,000 tons. Two finish-grinding mills, each with a capacity of 275,000 tons, will be installed in the principal marketing areas at Palembang and Telukbetung.

Iran.—Fars & Khuzestan Cement Co. completed its new Abyek plant with an annual capacity of 1.1 million tons. Shemal Cement Co. was planning a new cement plant near Abe-Ali about 28 miles northeast of Teheran. The 15.7-foot-diameter by 243-foot-long dry-process kiln equipped with a suspension preheater will have an annual capacity of 770,000 tons.

Iraq.—The Al Fuota plant about 35

miles west of Baghdad was completed in October with an annual capacity of 220,000 tons. Mosul Cement Public Co. will install a new dry-process kiln at its Bodoosh plant to increase capacity by 550,000 tons. The Government of Iraq was building a new cement plant about 100 miles south of Baghdad that will have an annual capacity of 2.2 million tons when the fourth kiln is completed early in 1978.

Ireland.—At Drogheda, Cement-Roadstone Holdings Ltd. planned to replace the old wet-process plant at its Platin works with an additional dry-process kiln having an annual capacity of 1 million tons. When completed in 1977, the net increase in production capacity will be 550,000 tons.

Italy.—In 1974, Italy became the largest cement-producing country in Western Europe. Cementerie Calabrolucane S.p.A. completed two new plants, each with an annual capacity of 550,000 tons, at Castrovillari and Matera. Cementizillo started operating a new plant at Fanna with a capacity of 495,000 tons. Cementeria e Manufatti Fratelli Colaiacovo Snc. installed a new kiln at its Gubbio plant that increased production capacity by 550,000 tons. Industria Siciliana Cementi S.p.A. increased the capacity of its Modica plant by 132,000 tons with the addition of a new kiln. Cementir-Cementerie del Tirreno S.p.A. was installing a new kiln at its Maddolani plant with an annual capacity of 1,265,000 tons. Completion was scheduled for 1975. S.A.C.C.I. S.p.A. was installing a new kiln at its Castelraimondo plant that will increase annual capacity by 275,000 tons when completed in 1975.

Kenya.—East African Portland Cement Co., Ltd., expanded its Athi River Works capacity with a new kiln. Bamburi Portland Cement Co., Ltd., was installing a new kiln with an annual capacity of 700,000 tons at its Bamburi plant. Completion was scheduled for mid-1976.

Korea, Republic of.—In March, Ssang Yong Cement Industrial Co., Ltd., completed installation of a 19-foot-diameter by 312-foot-long dry-process kiln equipped with a suspension preheater at its Donghae plant. Capacity of the plant was increased by 1.3 million tons to 3.3 million tons. The company embarked on another expansion program to raise the annual capacity of the Donghae plant by 6.1 million tons to a total of 9.5 million tons, one of the world's largest when completed in 1977. New equipment will include four 15.8-foot-diameter by 246-foot-long dry-process kilns with suspension preheaters. Tong Yang Cement Manufacturing Co., Ltd., was increasing the capacity of its Samchuk plant by 1.8 million tons to 2.9 million tons. Completion was scheduled for 1977. Hanil Cement Manufacturing Co., Ltd., was installing a new dry-process kiln utilizing auxiliary burners for precalcination in the suspension preheater at its Tan-yang plant. Capacity will be increased by 1.1 million tons. Hyun Dai Cement Co., Ltd., installed a 16-foot-diameter by 230-foot-long dry-process kiln equipped with a suspension preheater at its Tan-yang plant with a capacity increase of 770,000 tons. Chung Buk Cement Manufacturing Co., Ltd., plans to expand production capacity of its Jechun plant.

Lebanon.—Société des Ciments Libanais increased production capacity of its Chekka plant by 220,000 tons to 1.5 million tons during the year. The company planned to install a new kiln that will increase annual capacity by another 715,000 tons.

Malagasy Republic.—A $23 million cement plant near Antsirabe was planned to be built with Yugoslav-West German cooperative assistance.

Malta.—Hydrocarbon Industries Ltd., Malta Development Corp., and Maltese Falcon Cement Ltd. planned to build a $35 million cement plant with an annual capacity of 365,000 tons in Malta. Completion was scheduled for mid-1978.

Mexico.—Cementos Tolteca S.A. acquired three plants near the Pacific coast during 1973. The company started operating the new kiln at its Atotonilco plant, that increased the annual capacity by 600,000 tons. Cooperativa Manufacturera de Cemento Portland La Cruz Azul S.C.L. completed expansion of its plant at Lagunas, Oaxaca, increasing annual capacity by 330,000 tons. Equipment included a 12.5-foot-diameter by 350-foot-long dry-process kiln with a two-stage preheater. The original kiln was scheduled to be dismantled and the other old kiln, 10 feet in diameter by 360 feet long, will be modernized with installation of a preheater. The company was installing a 17-foot-diameter by 270-foot-long dry-process kiln with a preheater at its plant in Ciudad Cruz Azul, Hidalgo. Completion was scheduled for early 1976. Cementos Anahuac S.A. completed an expansion project at its plant in Tlalnepantla that increased annual production capacity by 700,000 tons. Cementos Apasco S.A. experienced delays in erecting a new kiln at its Apaxco plant because of material shortages. When completed in the spring of 1975, annual capacity of the plant will be increased to 1.5 million tons. Work was continuing under similar difficulties erecting the new 1,320-ton-per-day kiln at the Cementos Veracruz S.A. plant at Orizaba.

Morocco.—Cimenterie Maghrebine, a new company formed as a joint venture between the Moroccan and Algerian Governments, was planning a cement plant with an output of 1 million tons at Oujda.

Mozambique.—Companhia de Cementos de Moçambique ordered equipment for a new plant at Lourenço Marques and for a plant expansion in Beira.

Nepal.—In early 1975, Himal Cement Co., Ltd. planned to start operation of its new wet-process plant with an annual capacity of 66,000 tons at Chobhar. Nepal's Bureau of Mines expected to complete a project report in 1975 for a new cement plant in Bhainse-Hetauda with a production capacity of 220,000 tons.

New Zealand.—New Zealand Cement Holdings Ltd. was installing the third kiln at its Westport plant that will increase production capacity by 165,000 tons when completed in October 1975.

Nigeria.—West African Portland Cement Co., Ld. (WAPCC) started construction of a new cement plant near Shagamu about 40 miles northeast of Lagos with an annual capacity of 650,000 tons. Completion was scheduled for 1976. The Associated Portland Cement Manufacturers Ltd., parent company of WAPCC, together with the Nigerian Government as principal shareholders, were forming a new company to build a cement plant near Ashaka where the railroad crosses the Gongola River about midway between Jos and Maidurgi. The two-kiln, dry-process plant will have an annual capacity of 650,000 tons when completed in 1977.

Oman.—By decree of the Sultan of Oman, a cement plant will be built in that country. Cement Holding A.G. and Associated Portland Cement Manufacturers Ltd. announced plans to erect the country's first cement plant.

Pakistan.—The Iranian Government was assisting in the construction of a cement plant at Kohat, Northwest Frontier Province, with an annual capacity of 300,000 tons.

Panama.—Taiwan Cement Engineering Corp. was building a new plant near Calzada Larga for the Panamanian Government with an annual capacity of 320,000 tons. The name of the new establishment was Empresa Estatal de Cemento "Bayano."

Paraguay.—The Ministry of Industry and commerce was accepting tender proposals to build a plant to supply cement for construction of Itaipu dam, the world's largest hydroelectric project, undertaken jointly by Brazil and Paraguay.

Peru.—On February 12, 1974, the Government of Peru expropriated the country's largest cement producer at Atocongo near Lima and nationalized Cementos Lima S.A.

Philippines.—Midland Cement Corp. built a plant at Bulingbing near Tanay in Rizal Province with a capacity of 600,000 tons. In March, the Holderbank Group acquired an interest in Pacific Cement Co., Inc. The 10-year-old plant at Surigao required considerable rehabilitation.

Portugal.—Companhia de Cimentos do Norte (CINORTE) was building a new plant at Souselas near Coimbra. Combined annual capacity of the two dry-process kilns will be 1.1 million tons when completed in 1975. Two plant expansions were planned for completion in 1976 that would increase the country's annual production capacity by 1.65 million tons: A new kiln at the Alhanda plant by Companhia Cimento Tejo S.A.R.L., and a new kiln at Outao near Setúbal by Secil-Comphania Geral de Cal e Cimento S.A.R.L.

Qatar.—In October, Qatar National Cement Co. completed installation of a new kiln that increased annual capacity by 218,000 tons to 254,000 tons at its plant in Umm-Bab.

Saudi Arabia.—Saudi Cement Co. was installing two new dry-process kilns at its Al Hassa plant between Al Hufut and Abqaiq that will increase annual capacity by 1.1 million tons. In addition, the company was modernizing its three existing kilns.

Singapore.—Ssang Yong Cement, Singapore Cement Manufacturing Co. Pte, Ltd., a joint venture between Ssang Yong Cement Industrial Co., Ltd., of the Republic of Korea and Singapore firms, was installing a 13-foot-diameter by 40-foot-long, 4,000-horsepower finish-grinding mill near deepwater transportation. When completed in late 1975, the plant will become Singapore's fourth clinker-grinding facility. Clinker will be supplied by Ssang Yong's Donghae plant in Korea.

South Africa, Republic of.—Cape Portland Cement Co., Ltd., was increasing the annual output capacity of its De Hoek plant by 500,000 tons. Completion was expected in June 1975. Anglo-Alpha Cement Ltd. planned to install a new kiln at its Dudfield plant to increase daily capacity by 2,200 tons. Completion was scheduled for mid-1977.

Spain.—La Auxiliar de la Construccion S.A. installed a new dry-process kiln at its San Feliu de Llobregat plant near Barcelona with an annual increase in capacity of 660,000 tons. Cementos Molins S.A. completed an expansion program with a new dry-process kiln that increased annual capacity of its San Vicente dels Horts plant by 990,000 tons. S.A. Española de Cementos Portland added a new dry-process kiln to its Yeles plant near Toledo, increasing production capacity by 440,000 tons. Five new kilns were under construction that will increase the country's annual production capacity by 4.1 million tons, as follows: Cia. Valenciana de Cementos Portland S.A. at Factoria "C" Buñol near Valencia (910,000 tons); Cia. Catalana de Cementos Portland S.A. at its Vallirama plant near Barcelona (420,000 tons); Portland Iberia S.A. at its Castillejo plant near Toledo (550,000 tons); Cia. General de Asfaltos y Portland Asland at Sagunto (1.1 million tons); and Uniland at Monjos (1.1 million tons).

Sweden.—A.B. Cement, the country's sole cement producer, was converting its Koping plant with annual capacity of 220,000 tons to manufacturing lime.

Switzerland.—In June, Bundner Cementwerke A.G. completed a new 1,760-ton-per-day kiln at its Untervaz plant, increasing annual capacity to 770,000 tons. Two old kilns will be modernized next year. Société des Chaux et Ciments de la Suisse Romande installed a new kiln with an annual capacity of 545,000 tons at its Eclepéns plant, increasing plant capacity by 187,000 tons. Two old kilns were transferred to reserve, and an old kiln at the Roche plant was permanently abandoned. A new kiln at the Siggenthal plant increased Portland-Cement-Werk Wuerenlingen-Siggenthal A.G. production capacity by 407,000 tons. In the spring, Cementfabric Holderbank started construction of a new plant at Rekingen-Mellikon, Aargau. The kiln with an annual capacity of 770,000 tons was scheduled for operation in spring 1975.

Tanzania.—The State Mining Corp. was seeking bids to build the country's second cement plant to be located near Tanga. Initial capacity of the plant is to be 275,000 tons, and completion was planned for 1977. A Yugoslav company is involved in the planning, and Tanzania was expecting Yugoslav-West Germany cooperative assistance. Plans were also made to expand the capacity of the Wazo Hill plant and build another new plant in Mbeya.

Taiwan.—Kvan Hsi Cement Corp. plans to establish a new cement plant near Kaohsiung with an annual capacity of 1.3 million tons. Cheng Tai Cement Corp. was expanding production capacity of its plant at Tsoying with addition of a 13.5-foot-diameter by 195-foot-long dry-process kiln equipped with a suspension preheater. Completion was scheduled for mid-1975. Chia Hsin Cement Corp. was installing a 15-foot-diameter by 220-foot-long dry-process kiln equipped with a suspension preheater. The additional production capacity was expected to be in operation by fall 1975.

Tunisia.—The Tunisian Government planned to build a new plant with an annual capacity of 770,000 tons at Gabes. It also reached an agreement in principle with the Algerian Government for a joint venture to build a cement plant with an annual capacity of 1 million tons at Thala near the Algerian border. Ciments Portland de Bizerte was planning to expand the capacity of its Bizerte plant by 71,000 tons.

Turkey.—Bolu Çimento Sanayii A.S. started operating its new plant near Bolu with an annual capacity of 550,000 tons. Unye Çemento A.S. completed its new plant at Ordu with production capacity of 550,000 tons. Nuh Çimento Sanayii A.S. installed a new kiln at its Hereke plant near Istanbul that increased the annual capacity by 440,000 tons. Mersin Çimento A.S. was constructing a plant at Mersin with an annual capacity of

1.1 million tons. Completion was scheduled for 1975. Akcimento Ticaret A.S. was installing a kiln at its plant near Istanbul, to increase production capacity by 550,000 tons when completed in 1975. Nidge Çimento Sanayii A.S. also expected to complete construction of a new kiln at its Nidge plant in 1975, to increase annual capacity by 300,000 tons. Five new plants were planned or under construction with completion expected in 1976 or 1977: Masiin Çemento A.S. at Aardin (580,000 tons), and Turkiye Çimento Sanayii A.S. near Kars (290,000 tons), Yozgat, Iskanderun, and Canakkale. Aslan ve Eskihisir Muttehit Çimento ve su Kireci Fabrikasi A.S. was installing a new kiln to double production capacity of its plant near Darica to 1.1 million tons when completed in 1977. The five new plants and nine plant expansions were expected to increase the country's production capacity to 19.1 million tons when completed by 1977.

United Arab Emirates.—Union Cement Co. was building a plant in Ras al-Khaimah with an annual capacity of 275,000 tons. Completion was scheduled for spring 1975. Norcem of Norway was providing technical assistance and will be responsible for operating the new plant. Sheikl Rashid planned to build a cement plant near Dubai with a capacity of 550,000 tons.

United Kingdom.—Aberthaw & Bristol Channel Portland Cement Co., Ltd., was installing a new kiln at its Aberthaw plant, to increase annual capacity by 330,000 tons when completed in 1975. A new kiln was under construction at the Ribblesdale Cement Ltd., plant in Clitherol, Lancashire, to increase production capacity by 363,000 tons; completion was scheduled for 1975.

Upper Volta.—Société Voltaique was building a clinker-grinding facility near Ougadougou with an annual capacity of 33,000 tons.

Venezuela.—C.A. Venezolana de Cementos increased the capacity of its Pertigalete plant to 1.8 million tons and was installing an additional 13.5 foot/12-foot-diameter by 450-foot-long wet-process kiln. The company was installing a 12-foot-diameter by 450-foot-long wet-process kiln at its Maracaibo plant that will increase annual capacity by 750,000 tons. C.A. Fabrica Nacional de Cementos was installing two grinding mills at its Ocumare plant: 13-foot-diameter by 37.5-feet-long, and 15-foot diameter by 44.5 feet long.

Yugoslavia.—Salonit Anhovo Industrija Gradbenega Materiala was expanding production capacity of its plant near Novo Gorica by 935,000 tons to 1.1 million tons.

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] Includes production from the Azores and Madeira Islands as follows, in thousand short tons: 1972: Azores—17, Madeira—33; 1973: Azores—22, Madeira—35; 1974: Azores—15, Madeira—34. The balance of output in each year was from continental Portugal.

[2] Year beginning March 21 of that stated.

[3] Included with Japan.

TECHNOLOGY

Fossil fuel energy consumed by the cement industry to produce 1 ton of clinker ranged from 3.5 million Btu to 11.8 million Btu and averaged 6.26 million Btu. An additional 1.39 million Btu in electrical energy (130 kilowatt-hours per ton) was required in the production of 1 ton of portland cement, mostly for grinding.[4] The total energy used to produce 1 ton of portland cement averaged 7.65 million Btu. The fuel cost of producing 1 ton of clinker at an inefficient wet-process plant was more than three times the fuel cost for an efficient dry-process plant.

Shortages of natural gas and fuel oil and sharp increases in coal and other fuel costs, particularly imported fuel oil, which quadrupled in cost, have impelled virtually all cement manufacturers to consider improving kiln thermal efficiency. Most of the significant advances in cement production technology have been made in Europe and Japan. While the cement industry in the United States was seeking ways to reduce labor costs by modernization and automation in the 1950's, European manufacturers were developing means to reduce fuel costs. The dry-process kiln with a four-stage suspension preheater first developed by Humboldt in West Germany in 1950 offered the best fuel economy. F.L. Smidth of Denmark and Polysius Corp., Humboldt Wedag, Krupp, and Buhler-MIAG of West Germany all developed four-stage suspension preheaters, all of which are available in the United States from equipment manufacturers. Where alkali in raw materials is a serious problem, dry-process kilns with two-stage and single-stage suspension preheaters are used, with reduced fuel efficiency but greater economy than the long dry-process kilns and wet-process kilns.

Japanese firms with license rights on West German four-stage suspension preheaters developed auxiliary burners in the preheater to increase calcination to about 90% to 95% prior to the feed entering the kiln. An important advantage of this process, in addition to improved fuel economy, is that kiln output can be increased. Two equipment manufacturers in the United States were negotiating licensing agreements with Japanese firms holding patents on the new process. National Cement Co., Inc., was the first company in the United States to try the new Japanese process. The company started cutting an old kiln approximately in half and installing a four-stage suspension preheater with auxiliary burners. When completed, the output of the kiln will be more than doubled, and fuel consumption will be reduced to less than 3 million Btu per ton. In terms of thermal efficiency, this will be the best in the United States and equal to many operating in Europe and Japan. Kiln units exceeding 8,000 tons per day in output were in operation, and it may be possible to attain 10,000 tons per day using the Japanese process.

---

[4] Based on information from the Energy Research and Development Administration. The Federal Power Commission calculated an average heat rate of 10,660 Btu per net kilowatt-hour from national average heat rates for fossil-fueled steam-electric plants (130 kwh/ton x 10,660 Btu/kwh=1,385,800 Btu/ton).

Some companies modified old kilns by enlarging the diameter of the feed end to permit a greater quantity of chains or other heat exchanger devices to reduce fuel consumption and increase output. Efficiency of wet-process kilns can be improved by the use of slurry thinner additives that reduce the viscosity of the slurry so that a feed with higher solids and lower water can be pumped into the kiln. In one instance, a 2% water reduction was achieved, accounting for a 7.5% decrease in Btu per ton consumption. At another plant, a water reduction of 3.3% was made, using a slurry thinner additive, with a corresponding 5.2% reduction in Btu per ton requirements.

In instances where certain raw materials require wet grinding, the slurry has been dried outside the kiln, using waste heat from kiln exhaust gases in a spray dryer. Use of the spray dryer in Denmark resulted in up to 30% increase in output and up to 12.5% lower fuel consumption.

In addition to utilization of heat from dry-process kiln exit gases in suspension preheaters, waste heat was used for drying raw materials and coal. The roller mill was becoming increasingly important in dry-process raw grinding because it was more amenable to combined grinding-drying than ball and rod grinding mills. The development of hydraulically loaded rollers, rather than spring-loaded rollers, made possible larger capacity roller mills. The roller mill can dry raw materials with 15% moisture, using kiln gas, while the maximum moisture that can be dried in a ball mill is 7%. Roller mills will grind feed from 2 to 5 inches in size, depending on mill size, compared with about minus ½ to ¾ inch for the ball mills. Horsepower requirements for roller mills are 70% to 80% of the requirements for ball mills. Roller mills operate at a much lower noise level than ball mills. Cost of roller wear is about 60% of the cost of ball mill media. In 1973, Flintkote installed the first roller mill in the United States at Glens Falls, N.Y. The 1,500-horsepower mill had an hourly capacity of 125 tons.

In 1974, four roller mills were installed: Medusa Cement Co. at Clinchfield, Ga.; Southwestern Portland Cement Co. at Fairborn, Ohio; Universal Atlas Cement Div. at Buffington, Ind.; and Illinois Cement Co. at La Salle, Ill. Four more roller mills were being installed for operation in 1975: Capitol Aggregates, Inc., at San Antonio, Tex.; Universal Atlas Cement Div. at Leeds, Ala.; Citadel Cement Corp. at Roanoke, Va.; and Kaiser Cement & Gypsum Corp. at San Antonio, Tex. Hourly capacities of the roller mills ranged from 90 to 165 tons with various horsepower requirements from 900 to 1,500. Maximum moisture dried ranged from 4% to 15%, and the maximum feed material size ranged from 2 to 4 inches.

Several companies were manufacturing portland pozzolan cement to reduce the fuel costs in producing cement. Fly ash, a waste product from burning coal, was interground with portland cement clinker replacing about 20% of the clinker. Basically a 20% reduction of fuel consumption was accomplished.

In 1959, the first cyclone-gravel bed filter system for removing dust particles from air discharged from clinker coolers was installed in West Germany. Since 1973, 6 U.S. companies have installed gravel bed filter systems, or have them in various stages of planning and construction, at 14 plants. Each installation consists of several equal-sized units connected by ducts. Hot discharge air from clinker coolers enters a primary chamber where velocity is reduced to remove coarse dust. Additional coarse dust is removed in a cyclone preseparator. Fine dust is collected on a horizontally arranged 4-inch-thick filter bed, consisting of uniform quartz grains about the size of No. 3 shot. Periodically, the filter media is automatically air-cleaned of entrained dust. Clinker dust collected is recovered. Reported advantages of the gravel bed dust collector are (1) the filter medium resists wear, (2) maintenance costs are low, (3) temperatures to 900° F and above can be withstood, (4) a relatively wide variation in dust particle size will not affect filter performance, (5) water spray systems are not required, and (6) no filter replacement is required. Performance of cyclone-gravel bed dust collectors meets Federal standards under the Clean Air Act that limit discharge of particulate matter from clinker coolers to 0.10 pound per ton of dry kiln feed.

Another innovation in clinker cooler dust abatement was developed in 1973, by Riverside Cement Co., at Victorville, Calif., and approved by Government pollution control agencies in 1974. A heat exchanger system was utilized that serves both as an air pollution control device and as a method of heat recovery for secondary kiln air. Establishing a closed system of air circulation through the clinker cooler rather than ventilating hot dusty air to the atmosphere, the air-to-air heat exchanger engineered by Smith Environmental Corp., El Monte. Calif., eliminates the need for a baghouse or other kind of dust collector. Hot dusty air from the clinker passes through cyclones to remove coarse dust, then into heat exchanger tubes and back to the cooler. Temperature of the hot air is reduced in the heat exchanger from 600° F to 200° F by atmospheric air flowing over the outside of the tubes carrying the heated air. Clinker dust accumulated at the bottom of the heat exchanger is recovered by a system of gravity tipping valves and a screw conveyor. Reported advantages of this system include (1) substantially lower capital expense, (2) lower maintenance cost, (3) lower power cost (a 75-horsepower reduction in exhaust fan requirements at a cost of $150 a year per horsepower is a savings of $10,750), and (4) a kiln fuel savings from use of 200° F secondary combustion air.

Chromium

By John L. Morning [1]

Strong demand and rising prices for chromium marked the year. Demand for chromium alloys established a record high, although consumption decreased in the fourth quarter. The chemical industry registered new highs in consumption of chromite and production of sodium bichromate. Rising chromite prices, removal of price controls, and high demand for chromium alloys brought numerous price changes during the year. Depending on the particular alloy, prices increased twofold to threefold.

r Revised.

Legislation and Government Programs.—Government chromium material inventories are shown in table 2. Included in the inventories is material sold but unshipped. This includes chemical-grade chromite, 205,000 tons; refractory-grade chromite, 583,000 tons; metallurgical-grade chromite 909,000 tons; and chromium metal, 365 tons.

During the year, the General Services Administration (GSA), under various disposal programs, sold 318,138 tons of chemical-grade chromite, 899,950 tons of metallurgical-grade chromite, 571,241 tons of refractory-grade chromite, and 3,194 tons of chromium metal. The metallurgical sale was the Government stockpile at Nye, Mont., acquired under the Defense Production Act, primarily during the 1950's. At yearend, no material was available for sale from Government stockpiles because congressional authorization is required for further disposal of excess chromium materials. Although GSA proposed various programs, no congressional action was taken.

Table 2.—U.S. Government chromium stockpile material inventories and objectives
(Thousand short tons)

	Objective	Inventory by program, Dec. 31, 1974			
		National stockpile	Defense Production Act	Supplemental stockpile	Total

[1] Data may not add to total shown because of independent rounding.

---

[1] Supervisory physical scientist, Division of Ferrous Metals.

Deliveries of chromite from Government stockpiles from current- or prior-year sale contracts were as follows: Chemical-grade chromite, 299,493 tons, metallurgical-grade chromite, 76,735 tons; refractory-grade chromite, 123,921 tons; and chromium metal, 3,020 tons.

Repeal of the Byrd Amendment, which allows chromium to be imported into the United States from Southern Rhodesia, was the subject of congressional debate throughout the year. The Senate passed a bill early in the year that essentially repealed the Byrd Amendment. In the House of Representatives, floor votes were repeatedly scheduled and then dropped. At yearend, the bill was withdrawn. At the start of the 94th Congress in 1974, the bill was reintroduced.

In October, the Environmental Protection Agency (EPA) proposed air quality standards for the ferroalloy industry. For chromium alloy production, a maximum pollution level of 0.51 pound of particulate per megawatt-hour would be established.

Considerable interest was shown in mineral economic stockpiles. During the 93d Congress, Representative Bennett, Chairman of the Seapower and Strategic and Critical Materials Subcommittee of the House Armed Services Committee, offered an economic materials stockpile bill.

The Secretary of the Interior advocated holding several years' supply of most strategic minerals, including chromium, in ready reserve stocks. The stockpiles would not be long-run solutions to mineral problems, but would be used as a bridge to get over a temporary situation.

Assistant Secretary of State for Economic and Business Affairs, Thomas Enders, testified before Congress that chromium, bauxite, and platinum were prime candidates for potential economic stockpiles. He also cautioned that there were serious problems associated with economic stockpiles that would have to be worked out. Early in 1975, the Ferroalloys Association recommended to Congress a long-term strategic metals stockpile policy for the United States.

A comprehensive study by EPA and The Ferroalloys Association on air pollution engineering and costs in the ferroalloy industry was published.[2] The study encompassed historical background, current uses and production, and future trends as well as ferroalloy manufacture, atmospheric emissions, description of control systems, emission control guidelines, economics of emission control, and recommended research and development programs.

Concern over the ability of the United States to secure adequate supplies of imported critical raw materials at reasonable prices resulted in a special task force to identify and assess potential threats to supplies of these commodities as a basis for effective policy decisions. The results of the study, which included chromium, was published late in the year.[3]

DOMESTIC PRODUCTION

Domestic mine production of chromite ceased in 1961 when the last Government Defense Production Act contract was phased out. However, the United States continued to be one of the world's leading chromite consumers in producing chromium alloys, refractories, and chemicals. The principal producers of these products were as follows:

Company	Plant
Metallurgical industry:	
Airco Alloys and Carbide Div., Air Deduction Co. Inc	Calvert City, Ky. Niagara Falls, N.Y. Charleston, S.C.
Chromium Mining & Smelting Corp	Woodstock, Tenn.
Foote Mineral Co	Keokuk, Iowa Graham, W.Va.
Interlake, Inc	Beverly, Ohio
Prairie Metals and Chemicals, Inc	Prairie, Miss.
Satralloy Corp	Alloy, W.Va.
Shieldalloy Corp., Division of Metallurg Inc	Newfield, N.J.

Company	Plant
Metallurgical industry:—Continued	
Union Carbide Corp	Niagara Falls, N.Y. Marietta, Ohio Alloy, W.Va.
Refractory industry:	
Basic, Inc	Maple Grove, Ohio
Corhart Refractories Co., Inc	Louisville, Ky. Pascagoula, Miss.
General Refractories Co	Baltimore, Md. Lehi, Utah
Harbison-Walker Refractories Co. (a division of Dresser Industries, Inc.)	Hammond, Ind. Baltimore, Md.
Kaiser Aluminum & Chemical Corp	Moss Landing, Calif. Columbiana, Ohio Plymouth Meeting, Pa.
North American Refractories Co	Womelsdorf, Pa.
Ohio Fire Brick Co	Jackson, Ohio
Chemical industry:	
Allied Chemical Corp	Baltimore, Md.
Diamond Shamrock Corp	Castle Haynes, N.C. Kearny, N.J.
PPG Industries, Inc	Corpus Christi, Tex.

Table 3.—Production, shipments, and stocks of chromium ferroalloys and chromium metal

(Short tons)

Total	427,431	257,619	455,382	20,630

[1] Includes chromium briquets, chromium metal, exothermic chromium additives, and other miscellaneous chromium alloys.

CONSUMPTION AND USES

Domestic consumption of 1,447,000 tons of chromite ore and concentrate containing about 438,000 tons of chromium was 4% higher than in 1973. Of the total chromite consumed, the metallurgical industry used 62.3%, the refractory industry 20.3%, and the chemical industry 17.4%. The metallurgical industry consumed 902,000 tons of chromite containing 290,000 tons of chromium in producing 427,431 tons of chromium alloys and metal. About 66.9% of the metallurgical-grade ore had a chromium-to-iron ratio of 3:1 and over, 14.0% had a ratio between 2:1 and 3:1, and 19.1% had a ratio of less than 2:1.

Producers of chromite-bearing refractories consumed 294,000 tons of ore containing about 71,000 tons of chromium. The chemical industry consumed 251,000 tons of chromite containing about 77,000 tons of chromium in producing 174,000 tons of chemicals (sodium bichromate equivalent).

Chromium has a wide range of applications in three consuming industries. In the metallurgical industry, its principal use is in stainless steel. Primarily because of a record year in manufacture of stainless steel, consumption of chromium alloys reached a record high of 585,000 tons. Stainless steel accounted for 75% of the total chromium alloys consumed, an increase of 65,000 tons compared with that of 1973.

In the refractory industry, chromium was used in the form of chromite primarily for the manufacture of refractory bricks to line metallurgical furnaces. Consumption of chromite for refractory purposes increased 13% compared with that of 1973.

The chemical industry consumes chromite for manufacturing sodium or potassium bichromate, the base material for a wide range of chromium chemicals. Chromite consumption in this industry increased 22% compared with that of 1973.

[1] Includes magnetic and nonferrous alloys.
[2] Includes 5,479 tons of chromium metal.
[3] Includes 1,090 tons of chromium metal.

STOCKS

Chromite stocks which decreased significantly in the 2 previous years decreased only 4% in 1974 despite the unprecedented demand for chromium. Metallurgical industry stocks remained at the same level as in the previous year, refractory industry stocks increased nearly 10%, and those in the chemical industry decreased 38%. Shipping problems, both rail and port loading, in southern Africa along with a record consumption year caused the drop in stocks in the chemical industry. At yearend, stocks represented about a 5-month supply in the metallurgical industry, a 7-month supply in the refractory industry, and a 3-month supply in the chemical industry.

Primarily because of record stainless steel production, producer stocks of chromium alloys decreased 47% and consumer stocks increased 11%.

Stocks of chromium chemicals (sodium bichromate equivalent) at producer plants increased from 6,858 tons in 1973 to 14,525 tons in 1974. Stocks in general were at a low level throughout the year, but rose sharply in last 2 months of the year.

Table 6.—Consumer stocks of chromite, Dec. 31

(Thousand short tons)

Industry	1970	1971	1972	1973	1974
Metallurgical	387	667	601	339	340
Refractory	235	233	160	154	169
Chemical	111	119	96	104	64
Total	733	1,019	857	597	573

PRICES

The year was marked by steeply rising prices both for chromite and for chromium alloys. The published Soviet chromite price began the year at $37–$39 per metric ton f.o.b. Black Sea ports and moved higher in March to $53–$58 per metric ton. Turkish ore was quoted at $37 per long ton delivered Atlantic ports in January, and shortly thereafter moved to $50 per long ton f.o.b. Turkey. At midyear, the price rose to $60 per ton and in September, to $65 per long ton. South African ore began the year at $33–$34 per long ton delivered Atlantic ports and moved quickly to $37–$42 per ton. In March, the price was extended to $37–$44 per long ton. At midyear, the price was requoted at $50–$60 per ton, but in September the price was lowered to $47–$52 per long ton for the balance of the year.

Domestic chromium alloy prices began the year under regulation by the Cost of Living Council. Prices of imported chromium alloys at the beginning of the year were lower than domestic prices, but in the first quarter of the year rapidly increased by 4 to 5 cents per pound of chromium higher than domestic material. Domestic low-carbon prices were increased in February. After the Cost of Living Council deregulated ferroalloy prices in March, domestic producers increased most chromium alloy prices to about that of imported alloys. Throughout the balance of the year, numerous price changes were announced for both domestic and imported chromium alloys with imported alloys generally leading the change and at substantially higher prices than for domestic alloys. Prices of chromium alloys in January and December were as follows:

Material	*Cents per pound of chromium*	
	Jan. 1, 1974	Dec. 31, 1974
U.S. charge chromium	22–28	50
U.S. high-carbon ferrochromium	28.7	54
Imported charge chromium	21–21.5	65–75
U.S. low-carbon ferrochromium (0.05% carbon)	85.0	100
Imported low-carbon ferrochromium (0.05% carbon)	84.0	140–148
Simplex	([1])	85
	Cents per pound of product	
Aluminothermic chromium metal	153	230
Electrolytic chromium metal	153	230

FOREIGN TRADE

Exports of chromite were about the same as in 1973, but reexports increased nearly threefold compared with those of 1973. Major export shipments were to Canada (71%), Mexico (8%), Venezuela (8%), Australia (6%), and Peru (6%). Small quantities were shipped to three other countries. Reexports were shipped to four countries: Mexico (46%), Canada (43%), and Sweden (10%) received most of the shipments.

Ferrochromium exports to 17 countries decreased 52% compared with 1973 to 7,245 tons valued at $3,765,000. Canada

(50%), Mexico (28%), and West Germany (8%) were the leading recipients of the shipments.

Chromium and chromium alloys (wrought and unwrought) and waste and scrap exports totaled 1,251 tons valued at $2,258,000. Of the 30 countries receiving shipments, Brazil accounted for 27%, Canada, 12%, the United Kingdom, 11%, Argentina, 5%, the Netherlands, 5%, and West Germany, 5%.

Exports of pigment-grade chromium chemicals totaled 217 tons valued at $506,000. Canada (44%), the United Kingdom (24%), and Australia (15%) received 83% of the shipments; the balance was dispersed among 19 other countries. Exports of non-pigment-grade chemicals totaled 2,657 tons valued at $3,630,000. Canada received 28%, Australia, 15%; the Republic of Korea, 10%; and 38 countries received the balance.

Exports of sodium dichromate decreased 15% compared with that of 1973, falling to 10,550 tons valued at $3,284,000. Canada was the leading recipient with 51% of the shipments, and 35 other countries accounted for the balance.

Imports of chromite in 1974 increased 18% in quantity and 36% in value compared with 1973 totals. Imports increased 39% from the Philippines, 23% from the U.S.S.R., and 13% from the Republic of South Africa, and decreased 8% from Turkey.

Imports of ferrochromium established a new yearly record of 161,573 tons, an increase of 4% over that of 1973. The Republic of South Africa supplied 43% and Japan supplied 15% of the low-carbon ferrochromium imports. Eight other countries supplied the balance. High-carbon ferrochromium was imported from the Republic of South Africa (38%), Southern Rhodesia (25%), Yugoslavia (18%), and Brazil (9%). The balance was supplied by eight other countries.

Ferrochromium-silicon imports decreased 42% to 7,553 tons valued at $2,045,000. The Republic of South Africa supplied 56% and Southern Rhodesia, 44% of the total.

Chromium carbide imports totaling 233 tons, valued at $1,132,000, decreased 24%. West Germany supplied 70% and the United Kingdom and Japan supplied the balance.

Imports of chromium metal, unwrought and waste and scrap, decreased to 1,960 tons valued at $5,388,000 from 2,690 tons valued at $6,080,000 in 1973. Of the seven countries supplying imports, the United Kingdom accounted for 56% and Japan, 32%.

Imports of chromium-containing pigments were as follows: Chrome green, 45 tons; chrome yellow, 4,360 tons; chromium oxide green, 504 tons; molybdenum orange, 477 tons; and zinc yellow, 1,832 tons. Total value of these products was $8.2 million. Chrome yellow accounted for 52% and zinc yellow for 24% of total value. The leading suppliers were Japan (41% of total value) and Canada (27% of the total value).

Sodium chromate and dichromate imports totaled 1,945 tons valued at $1,132,000, nearly doubling those of 1973. Of the nine countries supplying imports, Japan accounted for 55%; Taiwan, 14%; and Canada, 11%. Imports of potassium chromate and dichromate increased significantly to 456 tons valued at $345,000 compared with 6 tons in 1973. Japan supplied 99% of the total and three other countries supplied the balance. Strontium chromate received from five countries totaled 407 tons valued at $662,000. Canada supplied 76% of the total.

473.20	Zinc yellow	Do.

[1] Not applicable to countries with centrally controlled economies.

[2] Duty temporarily suspended on waste and scrap.

WORLD REVIEW

The first International Ferroalloy Congress (INFACON–74) was held in Johannesburg, Republic of South Africa, in April 1974. The purpose of INFACON was to stimulate technical interchange on all aspects of ferroalloy production. Much of the subject matter concerned chromium. The Congress was well attended; 342 delegates from 26 countries registered. A published proceedings of the conference was planned by INFACON–74, Private Bag 7 Auckland Park, Johannesburg, Republic of South Africa.

Brazil.—Cia de Ferro-Ligas da Bahia, S.A. (FERBASA) produced nearly 124,000 tons of beneficiated chromite in 1974 compared with 109,000 tons in 1973 and produced 35,000 tons of high-carbon ferrochromium and 2,200 tons of low-carbon ferrochromium. Chromite reserves in Brazil are primarily in Bahia where 30 million tons of 40% Cr_2O_3 chromite are estimated. FERBASA operates two mines near Campo Formoso where beneficiated production of 238,000 tons was forecast for 1975. Plans were moving ahead for production of 1.5 million tons of chromite over a 10-year period by Cia. de Mineração Serra da Jacobina (SERJANA). This new concern is owned 51% by FERBASA and 49% by Brazilian Chrome Resources Development Co., a consortium of Japanese firms.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Bulgaria, North Korea and North Vietnam may also produce chromite, but production is not reported and available information is inadequate for formulation of output estimates.

[2] Less than ½ unit.

[3] Exports.

India.—India's chromite production in 1973 declined to 317,000 tons from 325,000 tons in 1972. The drop in production was attributed to monsoon rains in Orissa, delays caused by removal of excessive overburden, lack of ore haulage units, and lack of explosives. Of the 1973 production, Orissa accounted for 97% of the output. India's chromite exports increased from 69,000 tons in 1972 to 273,000 tons, all to Japan. Ferrochromium production in 1973 totaled 5,126 tons, well below the rated capacity of 30,000 tons. Exports totaled 1,347 tons mainly to Japan.

Japan.—Orissa Mining Corp. Ltd., India's largest chromite ore exporter, contracted to supply Marubeni Corp., purchasing agents for the Japanese firms of Nippon Kokan KK and Showa Denko KK, with 200,000 tons of chromite from January 1974 to June 1975. The price was believed to be $41 per ton f.o.b.

Nippon Kokan completed construction of a 56,000-ton-per-year high-carbon ferrochromium plant at Toyama. The furnace was rated at 35 megawatts.

Malagasy Republic.—Compagnie Minière d'Andriaména (COMINA), owned largely by Pechiney-Ugine Kuhlmann (France) with a 20% participation by the Malagasy Government, operated Madagascar's only chromite mine. COMINA operates on a 567-square-mile concession area that contains 30 separate deposits containing about 5 million tons of exploitable ore. COMINA has shown interest in construction of a ferrochromium plant providing the government builds a hydroelectric powerplant.

About 360 chromite outcrops were discovered in the mining district north of Andriamena. The Bureau de Recherches Géologiques et Minières (BRGM) of France, Compagnie Financiere Eurafricaine (subsidiary of Anglo American Corp. of South Africa Ltd.) and Japanese interests were jointly conducting a geological survey and drilling campaign on an area of about 2,200 square miles. The largest outcrop found measured about 700 feet long by 30 feet wide. It was estimated that ore beneath this outcrop could range to 1 million tons.

Pakistan.—Chromite is mined in the Muslimbagh area of Baluchistan Province from ore reserves that have been estimated at 2 to 3 million tons containing 48% Cr_2O_3. Over the past decade, production has averaged about 25,000 tons annually.

Philippines.—Output of chromite decreased 9% compared with that of 1973; 19% was classified as metallurgical ore and 81% as refractory ore. Acoje Mining Co. Inc., the sole metallurgical chromite producer, in 1973 mined and milled 289,000 tons of chromite to produce

108,000 tons of concentrate. The company shipped 118,000 tons of concentrate. Sufficient chromite ore was developed in 1973, beyond the previous limits of positive ore, to replace ore mined. At yearend, reserves totaled nearly 1.8 million tons of chromite. Consolidated Mines Inc. reported ore reserves of 8.8 million tons of refractory chromite in 1973.

Rhodesia, Southern.—Rio Tinto (Rhodesia) Ltd. reportedly was building a large-scale ferrochromium plant at Eiffel Flats, which was scheduled for completion at yearend. The new plant is located at the old Cam and Motor mine where housing, electricity, and rail facilities exist. Water supply will come from the new Claw Dam.

Rhodesian Vanadium Corp. (RVC) became part of Anglo American Corp. in November. RVC operates three chromite mines.

South Africa, Republic of.—Johannesburg Consolidated Investment Co. Ltd. (JCI) announced plans to form a South African company to produce and market high-carbon ferrochromium using a prereduced pellet (SRC) process. JCI entered into an agreement with Showa Denko KK of Japan to establish a 132,000-ton-per-year ferrochromium facility. The Japanese firm agreed to purchase a minimum of 34,000 tons annually.

That underground mines can be operated safely was pointed out when Chrome Corp. S.A. (Pty.) Ltd., a subsidiary of Union Carbide Corp., achieved a safety record of working 1.25 million man-shifts without a fatality including 1 million man-shifts for underground workers. The latter accomplishment occurred during the period of October 1951 to July 1974.

General Mining & Finance Corp. and Union Carbide Corp. announced a joint venture to build a 135,000-per-year ferrochromium facility in the Eastern Transvaal. General Mining will hold 51% equity in the new company and Union Carbide, 49%. General Mining will supply the new plant with chromium ore under a long-term contract. Union Carbide will provide the technology and engineering expertise for the facility. The new plant is scheduled for completion in the second half of 1976. Both General Mining and Union Carbide will act as marketing agents for the plant output.

Feralloys Ltd. (FL), subsidiary of Associated Manganese Mines of South Africa, announced plans to expand production facilities at its Cato Ridge and Machadodorp plants. FL produces manganese alloys at Cato Ridge and chromium alloys at Machododorp. The new facilities were scheduled for completion in 1977.

Vereeniging Refractories Ltd. constructed a new plant to increase production of basic brick (magnesite and chromium-magnesite). The new plant at the Main Works of Vereeniging will supplement current production owing to expansion of South Africa's steel industry. Wherever possible, mechanized equipment was installed to improve productivity.

Amcor Ltd. concluded long-term contracts for ferrochromium with two Japanese firms. Amcor announced that a third 48-megavolt-ampere (mVA) furnace was under construction at its Witbank plant, which will have a capacity of 55,000 tons per year.

Turkey.—According to the Turkish Chrome Producers Association, Turkey exported nearly 530,000 tons of chromite in 1974. The United States received 31% of the total, followed by France, 12%; Norway, 12%; and Switzerland, 10%. The public sector accounted for 56% of shipments; the private sector accounted for the balance. Over 69% of the shipments was from the port of Iskenderum. Ferrochromium exports totaled nearly 8,859 tons.

TECHNOLOGY

Japanese investigators first described production of high-carbon ferrochromium by prereduction of chromite in 1971. Developed by Showa Denko KK, the process was named the SRC system. Further technical points from pulverizing through smelting were described.[4]

A plant to produce ferrochromium-silicon was described.[5] Operating and production data together with metallurgical balances were also presented. A comparison was made between actual results and basic thermodynamic calculations with regard to a number of operating variables.

[5] Clark, P. W. The Production of Ferrosilicon-Chromium by the Single-Stage Process. INFACON–74 (Proceedings of the First International Ferro-Alloys Congress, Johannesburg, 22 to 26 April, 1974), 1975, pp. 275-280.

To better understand the mechanism of various reactions occurring during the smelting of high-carbon ferrochromium, a new technique was employed to measure the reduction of both iron and chromium to metal during smelting. At temperatures up to 1,500° C, reduction of chromite is controlled by diffusion of iron and chromium in the chromite spinel. At 1,500° C, the reduction rate of the chromium is increased by the fluxing action. In the presence of slag above 1,500° C, the reduction of chromite by carbon is rapid. These mechanisms are not independent of one another but have to occur in the order described.[6]

A process was described that produced low-carbon ferrochromium from South African Transvaal low-ratio chromite. Chromite fines and dolomite were melted in a slag furnace and reduced to 50%-55% chromium ferrochromium containing a maximum of 0.05% carbon using 75% ferrosilicon as a reductant. Costs for a hypothetical 20,000-ton-per-year plant located in the Transvaal were also given.[7]

Results of laboratory work and plant operations of a chromite pelletizing plant using the Lepol process were described.[8]

A careful dissection of an electric furnace revealed insights into furnace interior under melting conditions, the mechanism of melting and reduction processes, the mechanism of decarburization at the ore layer, composition of the slag layer, composition of the metal layer, and behavior of sulfur. Operations were suspended at an experimental electric furnace used to make high-carbon ferrochromium, the furnace was quenched with nitrogen, and resin was embedded in the material within the furnace interior.[9]

The role of chromium in human and animal nutrition was reviewed.[10] Essentially a review of the literature on the role of chromium in nutrition, this publication brings together studies on the subject and poses new problems to be solved.

Patent activity during the year concerned agglomeration of chromite to form a material for use in an electric furnace producing ferrochromium;[11] direct briquetting and reduction of oxide ores;[12] and methods of recovery of chromium values from chromite by solution methods.[13]

Clays

By Sarkis G. Ampian[1]

Clays in one or more of the classification categories (kaolin, ball clay, fire clay, bentonite, fuller's earth or common clay and shale) were produced in 47 States and Puerto Rico. Clay production was not reported in Alaska, the District of Columbia, Rhode Island, or Vermont. The States leading in output were Georgia, 7.7 million tons; Texas, 5.3 million tons; and Ohio, 4.3 million tons; followed in order by North Carolina, Alabama, and Pennsylvania. Georgia also led in total value of clay output with $204.0 million; Wyoming was second with $29.3 million. Compared with 1973 figures, clay production increased in 17 States and value increased in 33 States. Total quantity of clays sold or used by domestic producers in 1974 was 6% lower in tonnage and 19% higher in total value. The total value of clays produced was an alltime high. Modest increases in value per ton were reported for all clays in 1974 owing to increased labor, fuel, and material costs. The energy crisis or, more specifically, the increasing shortage and cost of fuels continued to cause much concern among clay producers and clay product manufacturers. Industrywide efforts were made to both economize and obtain standby fuels for their requirements. The costs of environmental protection equipment and environment restrictions, and rising capital costs, combined with the energy crisis, continued to adversely affect production during 1974.

Production of the speciality clays, kaolin, ball clay, fire clay, bentonite, and fuller's earth, all increased while common clay and shale declined. A downturn in construction rates that lowered the demand for materials manufactured from common clay and shale (brick, lightweight aggregate, vitrified clay pipe, clay floor and wall tile, etc.) was responsible for the decline. Production of kaolin increased 7%; ball clay, 7%; fire clay, 2%; bentonite, 8%; and fuller's earth, 8%. Common clay and shale decreased 9%.

Kaolin in 1974 accounted for only 10% of the total clay production but 49% of the domestic clay and shale value.

DOMESTIC PRODUCTION, PRICES, AND FOREIGN TRADE, BY TYPE OF CLAY

KAOLIN

Domestic production of kaolin in 1974 increased 7%, and the value increased 28%. The average unit value for all grades of kaolin in 1974 was $32.67 per ton, $5.41 higher than in 1973. Kaolin was produced at mines in 14 States. Two States, Georgia (75%) and South Carolina (12%), accounted for 87% of the total U.S. production in 1974, Alabama ranked third, Texas fourth, and Missouri fifth. Output in 1974 increased in Alabama, California, Georgia, Minnesota, Missouri, Nevada, and South Carolina and declined in Arkansas, Florida, North Carolina, Pennsylvania, Texas, and Utah. Colorado became a new producing State in 1974. No kaolin production was reported in 1974 in Arizona, Idaho and Indiana.

Kaolin is defined as a white, claylike material approximating the mineral kaolinite. It has a specific gravity of 2.6 and a fusion point of 1,785° C. The other kaolin-group minerals, such as halloysite and dickite, are encompassed.

During 1974 J. M. Huber Corp. completed construction of one of the world's largest spray dryers at its Wren, Ga., facility and developed a new mining area in the Edisto River region of Aiken County, S.C. Thiele Kaolin Co. brought a new mine and washer in Washington County, Ga., into full production. Thiele Kaolin Co. (Reedy Creek Division) and Albion Kaolin Co. added slurry production to their airfloat plants. Anglo-American Clays, a division of English China Clays, completed expansion of its plant in Sandersville, Ga. Thiele Kaolin Co. also put a large high-gradient magnetic separator (HGMS) on line during the year, making a total of four operating magnetic separators in the kaolin industry. Exploration geologists from several aluminum companies have increased their activities in Georgia and other areas of the country where kaolin is abundant. American Cyanamid Co. replaced bauxite with kaolin in its process for producing alum (hydrous aluminum sulfate).

Exports of kaolin, as reported by the U.S. Department of Commerce, increased from 732,000 tons valued at $30.5 million in 1973 to 849,000 tons valued at $42.1 million in 1974. The tonnage and value of the kaolin exported in 1974 increased 16% and 38%, respectively, over that shipped in 1973. The unit value per ton increased $7.86, which was attributable to both the greater percentage of higher quality paper-coating grades shipped and higher prices.

Kaolin was exported to 57 countries. The major recipients were Japan, 24%; Canada and Italy, 19% each; and West Germany, 17%. Exports to the remaining countries increased, except for those to Australia, Japan, and West Germany, which decreased 62%, 10%, and 3%, respectively. Kaolin producers reported the end use for their exports as follows: Paper coating, 55%; paper filling, 17%; refractories, 14%; rubber, 6%; and others, including fiberglass, paint, and plastics, 8%.

Kaolin imports in 1974 returned to the downward trend reported for a number of years by decreasing from 34,203 tons valued at $881,000 in 1973 to 19,111 tons valued at $750,000. The United Kingdom supplied 95%; Canada, nearly 5%; and three other countries, less than 0.5%.

Kaolin prices quoted in the trade journals in 1974 all advanced from 1973. Chemical Marketing Reporter, December 30, 1974, quoted prices as follows:

Waterwashed, fully calcined, bulk, carload lots, f.o.b. Georgia, per ton	$110.00
Partially calcined, same basis, per ton	110.00
Paper-grade, uncalcined, same basis, per ton:	
No. 1 coating	53.00
No. 2 coating	43.00
No. 3 coating	$42.00–43.00
Filler, general purpose, same basis, per ton	27.00–28.00
Delaminated, waterwashed, uncalcined, paint-grade, 1-micrometer average, same basis, per ton	91.00
Dry-ground, air-floated, soft, same basis, per ton	10.00
National Formulary, powder, 50-pound bags, 5,0000-pound lots, works, per pound	.07
National Formulary, colloidal, 150-pound drums, works, per pound	.36

The average unit value reported by domestic kaolin producers was $32.67 per ton, an increase of $5.41 above the 1973 value.

Table 2.—Clays sold or used by producers in the United States in 1974, by State[1]

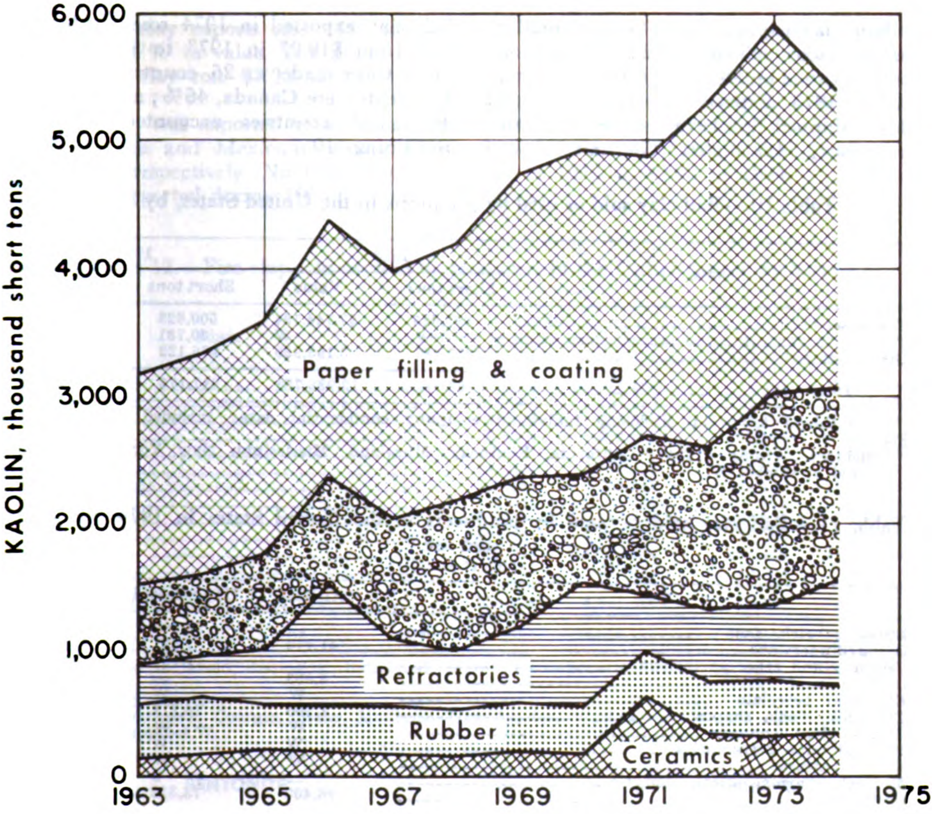

Figure 1.—Kaolin sold or used by domestic producers for specified uses.

BALL CLAY

Production and value reported for domestically mined ball clay in 1974 increased 7% and 9%, respectively. Tennessee mines provided 61% of the Nation's output, followed in order of output by Kentucky, Mississippi, Texas, Maryland, New York,[2] California, and Arizona. Production in Kentucky, Maryland, Mississippi, Tennessee, and Texas increased over that reported in 1973 while California and New York production decreased.

Ball clay is defined as a plastic, white-firing clay used principally for bonding in ceramic ware. The clays are of sedimentary origin and consist mainly of the clay mineral kaolinite and sericite micas.

In 1974 H.C. Spinks Clay Co., Inc. completed its drying and grinding facility at Gleason, Tenn. This facility expands production capacity for air-floated and mechanically dried clays and eliminates costly hauling from its Gleason area mines to other plants.

The average unit value for ball clay reported by domestic producers rose in 1974 to $17.34 per ton, an increase of $0.46 per ton. Chemical Marketing Reporter, December 30, 1974, listed ball clay prices unchanged from 1973 as follows:

Domestic, air-floated, bags, carload lots, Tennessee, per ton	$18.00–$22.00
Domestic, crushed, moisture-repellent, bulk, carload lots, Tennessee, per ton	8.00– 11.25
Imported, air-floated, bags, carload lots, Atlantic ports, per ton	70.00
Imported, lump, bulk, Great Lakes, per ton	40.50

---

[2] The famous Albany slip clay is included with ball clay solely for statistical convenience.

Ball clay exports in 1974 amounted to 131,000 tons valued at $2.9 million compared with 114,000 tons worth $2.2 million in 1973. Exports increased 15% over those shipped in 1973, while the value was nearly 34% higher. The unit value of ball clay exported in 1974 rose $3.16 per ton, from $19.27 in 1973 to $22.43. Exports were made to 26 countries: Major recipients were Canada, 46%; and Mexico, 44%; 24 countries accounted for the remaining 10%.

FIRE CLAY

Fire clay sold or used by domestic producers in 1974 was reported at 4,140,841 tons valued at $41.1 million. Fire clay is defined as detrital material, either plastic or rocklike, containing low percentages of iron oxide, lime, magnesia, and alkalies to enable the material to withstand temperatures to 1,500° C or higher. Fire clay is basically kaolinite but usually contains other materials such as diaspore, ball clay, bauxite clay, and shale. Fire clays commonly occur as underclay below coal seams and are generally used for refractories. Some fire clay was previously reported in other end uses.

Fire clay production was reported in 1974 from mines in 20 States. The first four States in rank, Ohio, Missouri, Pennsylvania and Alabama, accounted for 79% of the total domestic output.

General Refractories Co., U.S. Refractories Div., announced plans to expand its Gary plant to include a $2 million clay and alumina specialties plant. The new plant was scheduled for completion by the end of 1975.[3]

Exports of fire clay increased from 196,000 tons worth $3.8 million in 1973 to 224,000 tons valued at $6.0 million in

---

[3] Journal of Metals. Metallograms-Plan $2 Million Alumina Specialties Plant. V. 26, No. 11, November 1974, p. 10.

1974. Fire clay exports rose 14% in tonnage and 57% in value. The price of exported fire clay rose $7.22 to $26.71 per ton.

Fire clay was exported to 46 countries, with Canada and Mexico receiving 42% and 34%, respectively. No imports of fire clay were reported during 1974.

There are no price quotations in domestic journals for fire clay, but the per ton value reported by producers ranged from $2 to about $10. The reported average unit value for fire clay produced in the United States increased 12%, from $8.89 per ton in 1973 to $9.92 in 1974.

BENTONITE

Bentonite production in 1974 increased 8% in tonnage and 26% in value over that of 1973. A general increase in domestic consumption, particularly in iron ore pelletizing, drilling mud, animal feed, and waterproofing and sealing, was noted along with an overall increase in exports.

Bentonite was produced in 13 States. Increased bentonite production was reported for all States except Alabama, Arizona, Missouri, Texas, and Utah.

Generally, the high-swelling or sodium bentonites are produced chiefly in Wyoming, Montana, and South Dakota. The calcium or low-swelling bentonites are produced in the other States.

In 1974, Black Hills Bentonite Co. began production at a major new bentonite operation situated in Washakie County, north central Wyoming. This project consisted of developing a bentonite mining area near Ten Sleep and erecting a processing plant at Worland. The company's annual capacity has been reportedly doubled to 400,000 tons.[4] Industrywide improvements were made in environmental controls systems and in automating, bagging, and handling procedures.

On December 30, 1974, Chemical Marketing Reporter quoted bentonite prices as unchanged from 1973. Domestic, 200 mesh, bags, carload lots, f.o.b. mines, was priced from $15.50 to $16.00 per ton; and imported Italian white, high-gel, bags, 5-ton lots, ex-warehouse, $337.60 ($0.1688 per pound) per ton. The average unit value reported by domestic producers for bentonite sold or used in 1974 was $13.28 an increase of $1.94 from the $11.34 average of the previous year. Per ton values reported in the various producing States ranged from $4 to $36 but, as in 1973, the average value reported by the larger producers was near the Wyoming average figure of $12.58.

Bentonite imports in 1974, including chemically activated material, totaled 3,639 tons valued at $699,000, compared with 2,670 tons valued at $243,000 in 1973.

---

[4] Skillings, D.N., Jr. Black Hills Bentonite Co. Opens New Mine and Plant. Skillings' Min. Rev., v. 63, No. 45, Nov. 9, 1974, pp. 1, 6, 10.

The 3,599 tons of chemically activated bentonite was imported from six countries, with Canada supplying 25%; Mexico, 21%; Japan, 52%; and West Germany, Australia, and France the remainder. Special-purpose Italian bentonite was not imported in 1974.

Bentonite exports in 1974 increased from 551,000 tons in 1973 valued at $18.4 million to 714,000 tons valued at $28.1 milllion. Although the tonnage exported increased only 30% above that shipped in 1973, the value increased 56%. The greater increase in value was the result of the unit value of exported bentonite increasing $6.91 per ton, from $33.34 in 1973 to $40.25 in 1974. This increase in per ton value was attributed to a large increase in the amount of higher cost drilling mud and foundry-grade bentonites shipped. Exports in previous years consisted of a larger percentage of the lower cost pelletizing grades. Domestic bentonite producers were facing increased competition in foreign markets. Bentonite from the Greek Island of Milos was being blended with the U.S. clay for pelletizing Canadian taconite ores on a large scale.

Bentonite was exported to 83 countries, an increase of 6 from the previous year. The major recipients were Canada, 38%; West Germany, 10%; the United Kingdom, 9%; Australia, 8% the Netherlands, 5%; Singapore, 4%; Japan, Saudi Arabia, and Venezuela, 3% each; and the 74 others, 17%. Domestic bentonite producers reported the end use of their exports were foundry sand, 44%; iron ore pelletizing, 22%; drilling mud, 29%; and others, including animal feed, ceramics, ore treatment, and waterproofing and sealing, 5%.

FULLER'S EARTH

Production of fuller's earth in 1974 increased 8% in quantity and 32% in total value. The unit value assigned by domestic producers increased $5.38 in 1974 to $29.45 per ton. This increase was due to large increases in unit value by both the Florida and Georgia producers.

Fuller's earth production was reported from operations in 11 States, an increase of 2 States compared with 1973. The two top producing States, Georgia (40%) and Florida (34%), accounted for 74% of the domestic production. The other nine States accounted for the remaining 26%. Georgia, Mississippi, Tennessee, California, South Carolina, Texas, and Illinois showed gains in production while Florida and Utah declined slightly. The new producing States in 1974 were Missouri and Nevada.

Fuller's earth is defined as a nonplastic clay or claylike material, usually high in magnesia, which has adequate decolorizing and purifying properties.

Production from the region that includes Attapulgus (Decatur County), Ga., and Quincy (Gadsden County), Fla., is composed predominantly of the distinct lath-shaped amphibole clay mineral attapulgite. Most of the fuller's earth produced in the other areas of the United States contains varieties of montmorillonite.

Prices for fuller's earth were not publicly quoted in 1974, but the per ton value for attapulgite reported by producers ranged from $20 to over $63; montmorillonite prices ranged from $15 to under $35.

Exports of fuller's earth to 42 countries decreased from 58,000 tons valued at $2.7 million in 1973 to 56,000 tons valued at $3.2 million in 1974. Export tonnage decreased 3%, but its value increased nearly 18%. The unit value of exported fuller's earth rose $10.42 per ton. The major recipients were Canada, 38%; the United Kingdom, 21%; the Netherlands, 9%; Belgium-Luxembourg and France, 7% each; and other countries, the remaining 18%.

Imports of fuller's earth in 1974 were only 1 ton valued at $280 from Mexico.

COMMON CLAY

Domestic production of common clay and shale in 1974 totaled 44.9 million tons valued at $78.4 million. Common clay and shale represented 74% of the quantity and 19% of the value of the total clay and shale produced domestically in 1974. In addition, Puerto Rican production of common clay and shale was reported at 291,007 tons valued at $332,481. Domestic output in 1974 decreased 9% below that reported for 1973.

Common clays and shales are for the most part used by the producer in fabricating or manufacturing a product. Less than 10% of the total clay and shale output was sold. The average unit value for all common clay and shale produced in the United States and Puerto Rico in 1974 was $1.74 per ton, $0.14 more than in 1973. The range in unit value reported for the bulk of the output was from $1 to $2 per ton.

Common clay is defined as a clay or claylike material which is sufficiently plastic to permit ready mold and vitrification below 1,100° C. Shale is a consolidated sedimentary rock composed chiefly of clay minerals that have been both laminated and indurated while buried under other sediments. These materials are used in the manufacture of structural clay products, such as brick and drain tile, portland cement clinker, and bloated lightweight aggregate.

In 1974, a new brick plant capable of producing 60 million brick per year was put onstream at Galloway, Tenn. The plant was funded by a $2.8 million bond issue approved by the Galloway Industrial Board. A new tunnel kiln was put into production in Roanoke, Va., by the Webster Brick Co., Inc. The Cohoes, N.Y., lightweight aggregate plant of United States Steel Corp. was acquired by Norlite Corp., subsidiary of P. K. Keating Co. Keating is a Massachusetts-based aggregate and concrete producer. Norlite will be marketed throughout New England and New York.[5] Savings in fuel consumption and increased production at Georgia Lightweight Aggregates Co., Rockmart, Ga., was accomplished by installing lifters in its rotary kiln.

The output of the energy-intensive common clay and shale industry was curtailed by shortages of fuel, labor, and a downturn in construction in 1974. Industrywide attention was focusing on coal firing as a possible escape from the high cost and shortages of oil and gas.

Exports of common clay and shale are not tallied by the U.S. Department of Commerce. Most countries have local deposits of either clays or shales which are adequate for manufacturing structural clay products, cement clinker, and lightweight aggregates, and thus have no need to import such materials.

[1] Excludes Puerto Rico.
[2] Data may not add to totals shown because of mines having more than one kind of clay.

CONSUMPTION AND USES

The manufacture of heavy clay products (building brick, sewer pipe, drain, structural, and other tile), portland cement and clinker, and lightweight aggregate accounted for 37%, 20%, and 16%, respectively, of the total 1974 domestic consumption of clays. In summary, 74% of all clay produced in 1974 was consumed in the manufacture of these clay- and shale-based construction materials. The foregoing clay tonnage relationships were similar to those reported for 1973. The utilization of clays in 1974 for heavy clay products and portland cement decreased 8% and 5%, respectively, from that reported in 1973.

Heavy Clay Products.—The values reported for shipments of heavy clay products in 1974 declined 10% to $695 million from the 1973 value of $773 million. The trends in corresponding quantities were less consistent. Thousand-unit counts for building or common face brick decreased 23% in 1974 from those shipped in 1973 while shipments of glazed and unglazed ceramic tile and glazed brick and of clay floor and wall tile decreased 20% and 9%, respectively. The tonnage of unglazed structural tile increased 6%, and vitrified clay sewer pipe and fittings shipped during the year declined 21%. The value of these shipments, except for building brick and clay sewer pipe which decreased 17% and 3%, respectively, all remained unchanged.

Lightweight Aggregate.—Consumption of clay and shale in the making of lightweight aggregate declined in 1974 to 10,030,758 tons. This was a 14% decrease below the 11.7 million tons used in 1973, which was an alltime high.

The tonnage of raw material mentioned in tables 20 and 23 for lightweight aggregate production refers only to clay and shale and does not include the quantity of slate and blast furnace slag similarly used. In 1974, a total 983,196 tons of slate was expanded for lightweight aggregate, 10% below the 1973 figure of 1,092,021 tons. The National Slag Association reported the amount of expanded slag used for lightweight concrete aggregate and in block manufacture decreased 16% in 1974 from 1,560,000 tons in 1973 to 1,316,000 tons.

Refractories.—All types of clay were used in manufacturing refractories. Fire clay, kaolin, and bentonite accounted for 67%, 15%, and 13%, respectively, of the total clays used for this purpose. Bentonite was used primarily as a bonding agent in proprietary foundry formulations. Minor tonnages of ball clay (3%), fuller's earth, and common clay and shale (the remaining 2%) were also used, primarily as bonding agents.

The tonnage used for refractories in 1974 increased from 8% in 1973 to 9% of the total clays produced. This slight increase in the use of clay-based refractories continued for a third year, a reversal in the downward pattern set for a number of years. The increase was due primarily to both the continued expansion in refractory aggregate production and an upsurge in the manufacturing of more conventional brick-type refractories. Refractory aggregates are used mostly in plastic, gunning, ramming, and castable mixes.

Filler.—All clays are used to some extent as fillers in one or more areas of use. Kaolin and fuller's earth are the principal filler clays. Kaolin was used in the manufacture of a large number of products, such as paper, rubber, plastics, paint, and fertilizers. The other important filler clay, fuller's earth, was used primarily in pesticides and fertilizers. Clays in pesticides and fertilizers are used either as carriers, dilutents, or prilling agents.

Six percent of the clay produced in 1974 was used in filler applications. Kaolin accounted for 86%, and fuller's earth accounted for 6% of all the clay used for these purposes. The other clays accounted for the remaining 8%. The total amount of kaolin consumed by this end use category was essentially unchanged. In the individual categories, increases were recorded in paint (98%), paper filling (23%), fertilizers (22%), rubber (3%), and adhesives (2%). Decreases were noted in pesticides 1%, plastics 13%, paper coating 18%, and gypsum products 91%. Total quantity of fuller's earth used in insecticides and fungicides increased 2%.

Absorbent Uses.—Absorbent uses for clays, approximately 788,906 tons, consumed slightly more than 1% of the total 1974 clay production. Demand for absorbents in 1974 increased 9% from that reported for 1973. Fuller's earth was the principal clay used in absorbent applications; 97% of the entire output was consumed for this purpose. Bentonite was used to a lesser degree. Demand for clays in animal litter, representing 46% of the 1974 absorbent demand, increased 6% from that reported for 1973. Demand for use in floor absorbents, chiefly to absorb hazardous oily substances, represented the remaining 54% of absorbent demand and increased 11% from the 1973 figure.

Drilling Mud.—Demand for clays in rotary-drilling muds increased 7% in 1974, from 639,339 tons in 1973 to 681,755 tons. This increase in demand, mostly in exploratory gas well drilling and a lesser degree in oil well drilling, was spurred by the deregulation of "new" gas introduced into the interstate market after April 6, 1972. Drilling muds consumed slightly more than 1% of the entire 1974 clay production. Swelling-type bentonite is the principal clay used in drilling mud mixes, although fuller's earth or nonswelling bentonite is also used to a limited extent. Bentonite and fuller's earth accounted for nearly 100% of the total amount of clay used for this purpose. Small amounts of ball clay and common clay and shale were used in specialized formulations.

Floor and Wall Tile.—Common clay and shale, ball clay, fire clay, and kaolin, in order of demand, were used in manufacturing floor, wall, and quarry tile. This tile end use category accounted for less than 1% of the total clay production in 1974. Demand in 1974, 472,356 tons, increased 2% from that of 1973.

Pelletizing Iron Ore.—Bentonite is used as a binder in forming iron ore pellets. Demand, continuing the general trend, increased 12% in 1974 to 870,464 tons. This rise in the use of bentonite for iron ore pelletizing, reflecting an upturn in steel production, was accomplished in spite of inroads made by cheaper foreign bentonites into a traditional U.S. clay market. Of the total bentonite produced in 1974, about 32% of the swelling variety (an increase from 31% in 1973) was consumed for this purpose. U.S. deposits continued to be the major source for swelling bentonites.

Pottery.—The total demand for clays in the manufacture of pottery, sanitary ware, china/dinnerware, and related products, excluding clay flowerpots, accounted for 1% of the total 1974 clay output. The total clay demand, principally ball and kaolin clays rose slightly from 691,530 tons in 1973 to approximately 692,000 tons in 1974.

r Revised. NA Not available. XX Not applicable.

[1] Heated short of fusion, volatile materials thus being driven off in the presence of chemical changes, giving more stable material for refractory use.

[2] More or less plastic brick and materials which after the addition of water, if necessary, are rammed into place.

[3] Materials for domestic use as finished refractories, and all exported refractory material.

[4] Including calcined clay, ground brick and siliceous and other gunning mixes.

[5] Molten cast refractories are made by fusing refractory oxides and pouring molten material into molds to form finished shapes.

[6] Completely melted and cooled, then crushed and graded for use in a refractory.

[7] Includes shipments to refractory producers for reprocessing in the manufacture of other refractories.

Table 25.—Value of clay refractories shipped by consumer type

(Thousand dollars)

WORLD REVIEW

Australia.—Certain assets of Quality Earths Pty. Ltd., a mineral processor based in Sydney, were purchased by Steetley Co., Ltd., of the United Kingdom. These operations were to be merged with those of its other Australian minerals subsidiaries, Australian Clays and Industrial Minerals Ltd. and Commercial Minerals Pty. Ltd., which include the mining and milling of kaolin, ball clay, and flint clay.[6] English China Clay Corp. (ECC) began producing coating quality kaolins in an Australian plant.[7] Bulk Minerals Pty. Ltd. (jointly owned by North West Oil and Minerals NL and Clarence Oil and Minerals), a bentonite producer, purchased 80 acres of land, buildings and a plant at Port Pirie in South Australia.[8]

Total	[r] 15,010	16,886	17,715

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to countries listed, People's Republic of China, East Germany, Lebanon, Nigeria, Southern Rhodesia, and Yugoslavia also produced kaolin, but information is inadequate to make reliable estimates of output levels. Costa Rica, Guatemala, and Morocco produced less than 500 tons in each of the years covered by this table.

[2] Kaolin sold or used by producers.

[3] Includes kaolinitic clay.

[4] Excludes unwashed kaolin as follows in short tons: 1972—31,669; 1973—33,776; 1974—33,800 (estimated).

[5] Less than ½ unit.

[6] Year beginning March 21 of that stated.

[7] Data given are for ceramic and pottery clays.

Brazil.—Caulim Da Amazonia Ltda., located at Belem has acquired mining rights to an extensive deposit of proven high-grade kaolin. The company was erecting facilities, with a rated annual capacity of over 200,000 tons, to produce high-grade coating clays. The plant was scheduled for completion by late 1975 and shipments were expected to begin early in 1976. Euroclay (see section that follows on the Netherlands) was to provide distribution and technical services for marketing in Europe and Africa. Transportation of clay was to be by special bulk carriers on a fixed transport cycle.[9] In further kaolin activity the Kaolin Division of National Bulk Carriers, Inc., announced construction of its plant in the Amazon Basin and the Brazilian Government located and offered for sale another large kaolin deposit, 93 miles south of Belem on the Amazon River.[10]

France.—An agreement was concluded between Aluminium Pechiney (AP) and Aluminium Company of Canada, Ltd., a subsidiary of Alcan Aluminium Ltd., to set up a joint venture to construct a pilot plant near Marseilles to produce 20 tons of aluminum per day based on AP technology which uses raw materials other than bauxite. About $25 million was to be invested in the plant and it was due to be completed by mid-1976.[11]

Germany, West.—Morgan Refractories Ltd. of Neston, Chesire, and Thonwerke Ludwig KG of Koblenz have formed a joint company, Morgan Ludwig Feurfest GmbH, to manufacture and sell monolithic refractories.[12]

Guyana.—A longterm trade agreement was signed for the Government to supply kaolin, bauxite, and alumina (of unknown grade) to East Germany[13] and Japanese interests continued exploring and testing local kaolin clays.[14]

New Zealand (processed)[4]	683	1,136	1,206
Total	[r] 4,054,263	4,521,972	4,866,094

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Austria, Canada, the People's Republic of China, West Germany, Japan, and the U.S.S.R. are believed to have produced bentonite, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[2] Exports.

[3] Including bentonitic clay.

[4] In 1974, 4,382 short tons of unprocessed bentonite was reported among the mineral products of New Zealand; this is apparently in addition to the reported tonnages of processed bentonite. Comparable figures for 1972 and 1973 are not available.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, France, Iran, Japan, and Turkey have reportedly produced fuller's earth in the past and may continue to do so, but output is not reported and available information is inadequate to make reliable estimates of output levels. Similarly, no information is available on output in the centrally planned economy nations of Europe and Asia, but at least some of them also are presumably producing fuller's earth.

Hungary.—Large reserves of bentonite and kaolin were reported in the northeastern part of the country. The clays, found in hydrothermally altered rhyolite tuffs, were reported to be of high quality.[15]

Iran.—A $1.1 million contract has been awarded to Swindell-Dressler Co., a division of Pullman, Inc., by Iran Refractories Co. (IRC), for shuttle kilns and car-moving equipment for a refractory plant. IRC is a joint venture between Iranian partners and Harbison-Walker Refractories, Inc. (HWR). The new plant, designed by HWR was to have a rated capacity of 26,000 short tons, including a complete range of fire clay, high alumina, and basic refractory bricks for the Iranian market.[16]

Italy.—Production of activated bentonite was started at Süd-Chemie, Italia's new plant at Giba, Sardinia. The plant which took 1½ years to build is a subsidiary of Süd-Chemie, Munich.[17]

Malaysia.—The increased production of kaolin has come as the result of a new operation at Tapah in Perak State. This operation, which produces waterwashed grades, is controlled by a consortium of Japanese and Malay interests headed by Sanyo Pulp Co., a major Japanese consumer of kaolin and filling and coating grades.[18]

Netherlands.—Euroclay Handelmaatschappy BV of Rotterdam (owned by Georgia Kaolin Co. and Amberger Kaolinwerke GmbH of West Germany) has agreed to distribute paper-coating-quality kaolins produced by Caulim Da Amazonia Ltda. of Belem, Brazil, in Europe and Africa. Euroclay for years has provided the European paper industry with American coating clays, and the new agreement signifies an extension of its marketing program. Euroclay's decision was made to ensure long-term continuous supplies of high-quality American paper coating clays. Additional facilities were to be provided at the port of Rotterdam and at unspecified inland water sites to handle this new production from Brazil.[19] The Refractories Division of the Gibbons Dudley group moved into the European refactories market by acquiring a 50% interest in the Netherlands producer, Chamotte-Unie NV and forming a new company, Chamotte Gibbons Continental.[20]

South Africa, Republic of.—Octavi Mining Co. (Pty.) Ltd., a ceramics and refractory producer, planned to manufacture refractory brick and expand production of castables, moldables, etc., at its Belfast plant in Eastern Transvaal.[21] English China Clays South Africa (Pty.) Ltd. has opened an office in Pretoria with plans to beneficiate local clays and produce refractories for local markets.[22]

[22] Industrial Minerals. No. 86, November 1974, p. 44.

Turkey.—The country's visible and probable reserves of kaolin were reported as 150 million tons. Geological mapping on which mineral exploration and these reserves were based was an undertaking of the Mineral Research and Exploration Institute.[23]

United Kingdom.—English China Clay Ltd. (ECC) of St. Austell commissioned new refining, drying, and calcining plants and completed a plan covering river pollution. The river pollution plan involved constructing a 300 feet high dam at Kernick, comparable in height with the highest earth dam water reservoir in the United Kingdom, to settle some 3 million tons per year of micaceous residue associated with a production of 2.5 million tons of china clay. ECC was also expanding production of its calcined clay extender line, owing to the world shortage of TiO_2. Watts, Blake and Bearne and Co., Ltd., which has china and ball clay operations, mainly in Devon, was installing a new ball clay processing plant.[24]

In another undertaking, ECC acquired a 50% interest in International Drilling Fluids, excluding its activities in the United States and Canada. The company was formerly a wholly-owned subsidiary of Trans-Canada Resources of Calgary and is a major supplier of drilling mud.[25] Trans-Canada has a strong technical background and supplies engineering services and materials in the United Kingdom (both on and offshore) and overseas, including Spain, Portugal, the Netherlands (offshore), and the Middle East. As a consequence of this joint venture, the new company, International Drilling Fluids (U.K.) Ltd. will cover operations on and offshore in the United Kingdom and Ireland.[26]

Venezuela.—The Guyana Kaolin Co. built a processing plant south of the Eldorado River. The grade, rated capacity and destination of the plant output were unspecified.[27]

TECHNOLOGY

The U.S. Bureau of Mines and eight aluminum producers cosponsored research on extracting alumina from domestic materials that are plentiful, which could ease our dependence on imported bauxite. Using mini-pilot plant facilities at the Boulder City (Nev.) Metallurgy Laboratory, researchers were to investigate several methods for extracting alumina from clays, anorthosite, alunite, and dawsonite. Each participating company was to contribute $50,000 per year over the next 3 years to the program, and the cost to the Bureau was to be $400,000 per year.

Current work was proceeding on a Georgia kaolin using a nitric acid leaching process. Hydrochloric acid leaching of clay was scheduled for testing next, followed by anorthosite. The experimental miniplant, operational around the clock, can convert about 70 pounds of clay per hour to 25 pounds of alumina.[28]

A proposed timetable and funding for the Bureau's alumina miniplant program, with and without a cooperative effort, was published.[29] This publication also included a comprehensive treatise on the state of aluminum, the highlights of Bureau of Mines investigations on alumina from clays and other domestic sources, and a review of prior publications. In another work, the Bureau released revised and updated cost estimates for producing alumina from domestic raw materials by the nitric acid-ion exchange, hydrochloric acid-isopropyl ether extraction, potassium alum, and lime soda sinter processes.[30]

In a related work, the Georgia Department of Community Development under a grant from the Coastal Plains Regional Commission updated an earlier 1972 publication by issuing a detailed report on recovering alumina from Georgia kaolins.[31]

The work dealt in depth with significant events since 1972, Georgia kaolin reserves, potential processing methods, energy requirements and availability, water requirements and availability, transportation availability, and environmental considerations. A proposed State Constitutional amendment, and a sample ballot for referendum was included in an appendix. The amendment proposed a financial incentive to the first commercial producer of alumina or aluminum chloride from Georgia's vast kaolin deposits. Another evaluation of alternative methods of producing aluminum from non-bauxite ores was put forth. The discussion, including flowsheets, was concerned only with the Alcoa smelting, the Alcan, the monochloride, and the Toth processes.[32] A brief review was also attempted for those alumina from non-bauxitic ores projects that have reached, or are near to reaching a semicommercial stage of production.[33]

A review presented a survey of the past, present, and future of high-intensity wet magnetic separation (HGMS).[34] The principles involved were discussed, and the fundamental limitations on metallurgical performance were developed along with the influence of the liberation characteristics of the ore on separator performance. This review also traced the historical evolution of HGMS designs and depicted some of the currently available commercial separators. Another theoretical review article on HGMS was published.[35] Assessment of HGMS equipment and processing technology of the recently developed units was analyzed.[36] This work, while highlighting the removal of contaminants from kaolin slurries, also related this technology to the beneficiating of other industrial minerals, concentrations of metallic ores, desulfurization of coal, and cleanup of effluent streams.

The properties, handling, and economics of kaolin slurries used by the paper, paint, and rubber-plastics chemists were discussed.[37] A similar work was published on the role of fillers in plastics composites.[38] A treatise in three sections, mineralogy, deposits, and use of kaolins, was added to the literature.[39] The mineralogy section emphasized the difficulties encountered in classifying the kaolinite group of minerals and gives details of the various characterization methods used. The section concerned with deposits deals with the origin of the ores, without discussing genetic characteristics. The section on uses deals with economics which specifies the different grades required by users, and also gives information on the use of kaolins, especially in the paper industry. An identical work, highlighting the paper kaolins was added to the French literature.[40]

Newly designed stability diagrams coupled with a thermodynamic treatment show that in average river water halloysite and kaolinite are stable with respect to K-feldspar, albite, and nepheline. By contrast in present seawater, kaolinite alone is stable in a system containing kaolins plus K-feldspar or albite but both halloysite and kaolinite are stable in a system of kaolins and nepheline. Geological occurrences of kaolinite and halloysite in modern and ancient weathered products are consistent with these theoretical interpretations.[41] Addition of quercetin, an organic flavone ($C_{15}H_{10}O_7$), to aqueous solutions containing silica and aluminum and adjusted to final pH's from 6.5 to 8.5 produced a 1:1 aluminosilicate precipitate which, after 6 to 16 months of aging in solution at 25° C, contained as much as 5% well-formed kaolin plates.[42] Similar solutions containing no organic material produced relatively amorphous precipitates with the same composition and stability but with substantially smaller amounts of crystalline material even after 2 years of aging. The

1.9 infrared band of kaolinite clay, due to the H-O-H bending made of water, variable in clays, was shown to be dependent on the hydration state of the clay.[43] These three papers should help clarify the geological mode of formation of kaolin group clays. The phases in the kaolinite-mullite reaction sequence were reexamined by infrared absorption spectrophotometry.[44] This work appears to eliminate the uncertainty about the identity of the Al-containing phase intermediate between metakaolinite (formed on dehydroxylation at≈500° C) and mullite (forming at≈950° C). The new phase was identified as an Al-Si spinel. This work should contribute to the more efficient calcining of kaolins and producing refractory mullite grogs and crude aggregates from kaolin-bauxite mixtures.

A technique for identifying the fabric of kaolin clay by measurement of the monochromatic light intensity emanating from the analyzer of a polarizing microscope was described and evaluated analytically and experimentally.[45] This technique should help researchers in relating various phenomenological response characteristics (deformation resistance, permeability, etc.) of clay soils to their fabrics, or the geometrical relationships among individual particles or groups of particles. The kinetics of the adsorption of 2, 4–D from aqueous solution by Wyoming bentonites and their distribution within the clay's sheet structure was investigated.[46] The knowledge of these adsorption processes will aid in predicting the distribution of herbicides and fertilizers in the soil and aquatic environments.

Synthetic hectorite, purer than the natural clay was made from a relatively cheap and abundant natural source material, Montana talc. This method, reportedly cheaper than existing methods, involves calcining a talc and lithium oxide mixture at 1,400° to 1,800° F and then mixing with an aqueous solution of sodium silicate and carbonate (or hydroxide or bicarbonate) in given ratios. Autoclaving, follows from 8 to 16 hours, to give a desired clay composition—Si_{18} $Mg_{5.3}$ $Li_{0.66}(OH)_4$ O_{20} $Na_{0.66}$—with fluorine replacing some of the hydroxide group. The hectorite product gives a desirable rheology for oil thickening in mud, paint, and grease.[47]

A detailed discussion of Australian kaolin deposits in New South Wales, Victoria, South Australia, Queensland, Western Australia, and Tasmania were highlighted.[48] Included in the discussion was a State-by-State kaolin production table from 1967 to 1971 and a breakdown of its uses in Australian industry: Ceramics, 33.5%; refractories, 32.0%; paper, 24%; rubber, 4.5%; paint, 2.8%; and others, 3.2%.

The geomorphology, geological structure, stratigraphy, and economic geology of the Meigs-Attapulgus-Quincy district in Georgia and Florida, the leading producer of fuller's earth in the United States, was published.[49] A guidebook was prepared for a field conference sponsored by the Society of Economic Geologists (SEG) Inc. prior to the joint meeting of the SEG with the Geological Society of America, Miami, Fla., November 14–16, 1974.[50] The book dealt with the kaolin of the Macon-Gordon area (Georgia) and the fuller's earth of the Meigs-Attapulgus-Quincy district, in Georgia and Florida. The fuller's earth section was similar to the one referenced in footnote 49. The kaolin section covered the stratigraphy, structure, deposits, and preparation of kaolin for marketing in the area. Discussion of the kaolin deposits included definition and mineralogy, occurrence, origin, and exploration and evaluation of selected deposits. The preparation segment touched on mining, beneficiation, and uses and production.

A detailed discussion of modern refractory maintenance procedures for kilns was highlighted.[51] The discussion included sections on the planning, purchasing, receiving and storage, removal of old lining, installation of new lining, warmup, and operation. The installation section dealt with brick, castables, and plastics refractories. These refractories are usually clay-based materials. A similar in-depth study of furnace, ladle, pouring pad, nozzle, tundish, and pouring refractories for continuous casting of steel[52] was detailed in another article. The paper described changes in refractory technology involved in making continuous casting successful, discusses current patterns in refractory consumption, and predicts future trends.

DOMESTIC PRODUCTION

Bituminous coal and lignite production increased from 591.7 million tons in 1973 to 603.4 million tons in 1974. Despite the increase, an estimated loss in annual production of about 25 million tons occurred in 1974 because of a miners' strike in November and December during negotiations of a new wage agreement. In addition to the strike interruption, activities in the coal industry were unsettled because of uncertainties in the overall energy market resulting from tightened supplies of oil and natural gas and constraints on coal production from environmental requirements pertaining to air pollution and surface mining.

Underground production declined 22 million tons in 1974, primarily owing to the strike which had a much greater impact on output from deep mines than on that from surface mines. Surface mine production increased 34 million tons and accounted for 54% of total production. In 1974 production increased in nearly all Western States, but declined in most Eastern States.

This survey includes all bituminous coal produced in the United States except production from mines that produced less than 1,000 tons per year. All quantity figures represent short tons of marketable coal and exclude washery and other refuse. Statistics are final and based upon detailed annual reports of production and mine operation furnished by producers. For production not directly reported (chiefly that of small mines), accurate data were obtained from the records of State mine departments, which have statutory authority to require such reports. Thus, complete coverage of all mines producing 1,000 tons per year or more is reported.

---

[1] Industry economist, Division of Coal.
[2] Mining engineer, Division of Fuels Data.

The weekly and monthly estimates of production, summarized in tables 6 and 7, are based upon car-loadings of coal reported weekly by railroads, river shipments reported by the U.S. Army Corps of Engineers, reports from mining companies, and monthly production statements compiled by local operators' associations and State mine departments.

Employment increased from 148,000 men in 1973 to 167,000 men in 1974. Coal production per man per day for all miners of 17.58 tons in 1974 was identical to productivity in 1973 despite decreases in both underground and surface mine productivity. This occurred because of the large percentage increase in surface mine production.

CONSUMPTION AND DISTRIBUTION

Tables 40–45 summarize shipments of coal and lignite in 1974. Table 45 shows the quantitative changes in total tons by geographic division and States of destination from 1970 through 1974. The distribution data by consumer use do not necessarily conform to the consumption data because the latter represents actual use at consumers' facilities, whereas the distribution data represent shipments from mines, some of which were in transit or in consumers' storage. These distribution data are based on reports submitted quarterly to the Bureau of Mines by producers, sales agents, distributors, and wholesalers, who normally produce or sell 100,000 tons or more annually. Their reported tonnage accounted for 92% of the coal produced or shipped in 1974. To account for total industry shipments, estimates for the remaining shipments are included, based on data from the Federal Power Commission and other reliable coal statistical reporting agencies. Additional details of bituminous coal and lignite distribution for 1974 were published by the Bureau of Mines.[8]

PRICES

A combination of factors drove f.o.b. mine prices of coal sharply upward in 1974. The Arab oil embargo of 1973–74 resulted in a considerable increase in demand for coal and consequent higher prices. Imbalances in supply and demand were aggravated by distress buying in anticipation of the miners' strike late in 1974. The average f.o.b. mine value of coal increased from $8.53 per ton in 1973 to $15.75 per ton in 1974. The average price of coal at underground mines increased from $10.84 per ton in 1973 to $19.86 per ton in 1974. The average price at strip mines increased from $6.11 per ton in 1973 to $11.11 per ton in 1974. The average rail freight charge on coal increased from $3.71 per ton in 1973 to $4.71 per ton in 1974.

FOREIGN TRADE

In 1974, the United States exported 59.9 million tons of coal, an increase of 7 million tons compared with exports in 1973. Japan maintained its position as the principal U.S. foreign market with a 45.6%, share of total U.S. coal exports. Shipments of coal to Canada, Europe, and South America accounted for 22.9%, 26.5%, and 3.9%, respectively.

There was a 5-million ton increase in coal shipped from eastern coal producing districts in 1974. Shipments of higher sulfur coals from midwestern producing districts declined 8 million tons. Total shipments from Western States increased 15 million tons.

[8] Bureau of Mines. Bituminous Coal and Lignite Distribution for Calendar Year 1974. Mineral Industry Survey, Apr. 18, 1975.

TECHNOLOGY

Coal mining research is currently aimed at increasing productivity and unit operating capacities of mining systems without causing any adverse impacts on safety or the environment. Toward this end, the Bureau of Mines in 1974 began an intensive and long-range coal extraction and exploration program. Because of the geographic and stratigraphic distribution of coal resources, a continuing production mix from both surface and underground mining is needed. Accordingly, the near-term goal of the program is to develop technologies that will result in significant increases in production, productivity, and coal recovery with the present surface and underground mining methods.

In exploration research, emphasis is being placed on securing more definitive geologic and geochemical data on many coal deposits, particularly those in Western States. Although coal reserves are adequately identified for short-term policy and production needs, these data are needed to provide industry with better knowledge on which to base regional mining extraction plans, and also to assess factors that will determine the environmental impact of mining.

The environmental studies area will concentrate on developing criteria to measure the impact of mining on the ecosystem. Most of the environmental protection technology research will be integrated within the new mining system projects.

The major goals in the mining technology program are to increase the average production per shift from both conventional and continuous mining methods by increasing the reliability of existing equipment and to improve productivity substantially by automating or remote controlling as many operations as possible; to accelerate the use of longwall mining to increase the percentage of coal recovered and to mine efficiently and safely coal deposits at greater depths and under difficult strata conditions; to recover methane from the coal seam prior to mining to speed production by eliminating methane problems, and to make use of the methane; to develop mining systems that can economically recover 80% or more of thick and steeply pitching seams of coal in certain western deposits; to develop the technology to provide adequate protections of the surface environment from underground mining such as subsidence and water contamination; and to reduce the time required to open new mines and bring them to full production.

The Bureau of Mines major goal in advancing surface mining technology involves the integration of excavation and reclamation systems in order to reduce the environmental impact. Equipment developments will be undertaken where specialized needs are identified that would improve the efficiency of mining and reclaiming the surface. The Bureau is also exploring the feasibility of improving efficiencies of present large stripping equipment by automating the dig-haul-dump-spread cycle. Reclamation techniques are being developed that will be particularly adaptable to the arid and semiarid western coal regions.

Table 1.—Salient statistics of the bituminous coal and lignite industry in the United States

Item	1970	1971	1972	1973	1974
Production ----- thousand short tons --	602,932	552,192	595,386	591,738	603,406

1974	603,406	14,320	11,865	552,709	12,750	11,535

[1] Prior to 1973 the average heat content of the annual output of bituminous coal and lignite was measured at 13,100 Btu per pound. This value was based on an estimate made in 1949 (Bureau of Mines Information Circular 7538). In recent years this heat value has not been representative of the average unit heat value of the total annual coal supply because of the large annual increases in utilization of coal of lower heat values by the electric utility industry. The annual production values shown in this table are weighted averages of known and estimated Btu values of coal shipments to each major consuming sector. They include, for example, the Btu value of coal consumed at electric utility generating plants as reported to the Federal Power Commission and compiled by the National Coal Association. Currently, electric utility plants account for 70% of total domestic coal consumption. The averages for U.S. consumption exclude shipments overseas and to Canada, the preponderance of which comprises high-Btu-value metallurgical coal, thus accounting for the difference in values between total production and domestic consumption.

---

[1] Figures represent production and number of working days in that part of week included in calendar year shown.

[2] Average daily output for the working days in the calendar year shown.

[3] Data may not add to totals shown because of independent rounding.

[1] Figures are based principally upon railroad carloadings and river shipments supplemented by direct reports from certain local sources. These estimates include both coal shipped by truck and coal used at the mines, and the totals represent output for all mines producing 1,000 tons or more per year.

[2] Data may not add to totals shown because of independent rounding.

W Withheld to avoid disclosing individual company confidential data.

[1] Includes coal loaded at mines directly into railroad cars or river barges, hauled by trucks to railroad siding, and hauled by trucks to waterways.

[2] Includes coal used at mine for power and heat, made into beehive coke at mine, used by mine employees, used for other purposes at mine, and shipped by slurry pipeline in Arizona.

[3] Data may not add to totals shown because of independent rounding.

[4] Value received or charged for coal, f.o.b. mine. Includes a value, estimated by producer, for coal not sold.

[5] Less than 500 tons.

[e] Estimate. W Withheld to avoid disclosing individual company confidential data.

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by trucks to railroad sidings, and hauled by trucks to waterways.

[2] Includes coal used at mine for power and heat, made into beehive coke at mine, used by mine employees, used for all other purposes at mine, and shipped by slurry pipeline in Arizona.

[3] Data may not add to totals shown because of independent rounding.

[4] Value at average prices that might have been received if such had been sold commercially.

[5] Less than 500 tons.

[6] This is an extension of mine counted in Lewis County.

Table 19.—Underground mine data for bituminous coal, in 1974, by State
(Thousand short tons)

State	Number of mines	Production	Cut by hand and shot from solid	Cut by machines			Mined by continuous mining machines	Mined by longwall machines	Number of power drills and production										
				Quantity	Number of coal cutting machines	Average output per machine			Number of mines using power drills	Face or coal drills				Roof or rock drills					
										Handheld and post mounted		Mobile		Roof bolting			Other uses

[1] Includes all mines using belt conveyors 500 feet long or more for transporting coal underground.
[2] Data may not add to totals shown because of independent rounding.

Table 22.—Bituminous coal mechanically loaded underground in the United States, by type of loading equipment

(Thousand short tons)

Type of loading equipment	1973	1974
Mobile loading machines:		
Direct into mine cars or onto conveyors	13,537	7,173
Into shuttle cars	95,804	81,991
Continuous-mining machines:		
Onto conveyors	10,178	7,766
Into shuttle or mine cars	140,207	141,968
Onto bottom	28,215	21,563
Longwall machines	9,442	9,574
Scoops	(1)	6,564
Total	[2] 297,384	276,599

[1] Included with mobile loading machines in 1973.
[2] Data do not add to total shown because of independent rounding.

Table 23.—Comparative changes in underground mechanical loading of bituminous coal by principal types of loading devices in the United States, by State

Total	390,068	80	1,337	88,410	6,155	57,819	8,840	552,709

[1] Federal Power Commission.

[2] Bureau of the Census, U.S. Department of Commerce; Ore and Coal Exchange.

[3] Estimates based upon reports collected from a selected list of representative steel and rolling mills.

[4] Estimates based upon reports collected from a selected list of representative manufacturing plants.

[5] Estimates based upon reports collected from a selected list of representative retailers. Includes some coal shipped by truck from mine to final destination.

[6] The total of classes shown approximates total consumption. The calculation of consumption from production, imports, exports, and changes in stocks is not as accurate as the "Total of classes shown" because certain significant items of stocks are not included in monthly stocks. These items are stocks on lake and tidewater docks, stocks at other intermediate storage piles between mine and consumer, and coal in transit.

Table 41.—Stocks and days' supply of bituminous coal and lignite in the United States, in 1974, by consumer class

(Thousand short tons)

Date	Electric power utilities [1]	Oven coke plants	Steel and rolling mills	Other manufacturing and mining industries	Retail dealers	Total
			STOCKS

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Ecuador produces coal, but output was less than 500 tons annually in the years covered by this table.

[2] Revised to zero.

[3] Includes material reported in national sources as brown coal.

[4] Available sources report only lignite production; a small amount of bituminous coal may also be produced.

[5] Official sources report the aggregate of bituminous coal and anthracite; distribution to these separate grades is estimated from reported total.

[6] Output from Norwegian-controlled portion only. Output of that portion of Svalbard controlled by the U.S.S.R. is presumably included in the total output recorded for that country.

[7] Run-of-mine output.

[8] May include small amount of anthracite.

[9] Sales for year ending August 31 of that stated.

[10] Year beginning March 21 of that stated.

[11] Data include low-ranked coals, including some lignite.

[12] Year ending June 30 of that stated.

[13] Bituminous coal plus lignite for the People's Republic of China plus Pakistan.

[1] Total shipments by producers reporting sulfur content (76% of total U.S. production).

Coal-Pennsylvania Anthracite

By Dorothy R. Federoff [1]

All of the reported production of anthracite in 1974 originated in northeastern Pennsylvania. The anthracite region is divided geologically into four fields: Eastern Middle, Northern, Southern, and Western Middle. The area is also grouped into three trade regions: Lehigh, Schuylkill, and Wyoming.

A combination of circumstances resulted in an overall demand for anthracite that exceeded supply. An increased world demand for steel, an oil embargo, and a nationwide bituminous coal strike combined to open additional markets for industrial anthracite in the steel industry. Anthracite consumption by the steel industry in the United States increased 16% over that of 1973.

Production of anthracite in 1974 totaled 6.6 million short tons, a decrease of 3% from that of 1973. The decline in production was accelerated by the liquidation of a major anthracite-producing company in the Wyoming region. Consequently, the output of sizes for domestic heating dropped about 50%, creating a serious shortage of coal for space heating throughout the northeastern area. Because of the energy crisis, the Federal Bureau of Mines established an office at Wilkes-Barre, Pa., to help consumers obtain coal during the emergency.

Of the total output, 45% was recovered from culm and silt banks, 43% was produced at strip pits, 10% came from underground mines, and 2% was recovered at dredging operations. When compared with tonnages produced in 1973, underground production declined 9%, strip production 13%, and dredge coal recovery 66%. However, recovery from culm and silt banks increased 23%, somewhat compensating for the drop in strip and underground production and raising the total to within 3% of the tonnage produced in 1973.

The contraction of the industry, combined with increased costs of materials, labor, and transportation, increased prices well above the 1973 levels.

Total value of the 1974 output was $144.7 million, a 60% increase over that of 1973. The average value f.o.b. preparation plants for all sizes of anthracite, including dredge coal, was $21.87 per ton, compared with $13.22 per ton in 1973. The average value of pea and larger sizes increased $11.65 per ton ($18.76 to $30.41), and the average value of buckwheat No. 1 and smaller sizes increased $7.63 per ton ($10.90 to $18.53).

Apparent consumption of Pennsylvania anthracite in the United States in 1974, calculated as production minus exports, excluding that exported to West Germany for use by the U.S. Armed Forces, totaled approximately 5.4 million tons, compared with 5.7 million tons in 1973, a decrease of 4%. Overall consumption was as follows: Space heating, 47%; electric utilities, 28%; coke making, 8%; sintering and pelletizing, 7%; colliery fuel, less than 1%; and other industrial uses, 10%.

According to the U.S. Bureau of the Census, exports in 1974 totaled approximately 735,173 short tons, an increase of 3% over the 716,546 tons shipped to foreign countries in 1973. Of that total, 65% was shipped to Canada, 27% was exported to Europe, and the remainder went to other countries. A more accurate measurement of exports can be obtained by adding the quantity shipped for use by the armed forces in West Germany to the tonnage reported by the Bureau of the

---

[1] Mineral specialist, Division of Fuels Data.

Census. This computation indicated that 1,169,468 tons was actually exported, an increase of approximately 1% over that in 1973.

The Pennsylvania anthracite mining industry worked an average of 219 days in 1974, compared with 234 days in 1973. The suspension of operations by one of the major companies in the first half of 1974 and a drop in river dredging operations resulted in a reduced labor force. The work force averaged 3,847, an employee decline of approximately 6% from that of 1973. Of that total, 1,376 were employed at strip pits, 594 at underground mines, 390 at culm and silt recovery, 20 at dredging operations, and 1,467 at breakers and other surface operations.

Although there were declines in total production and in the number of men employed daily, the productivity rate in average tons per man-day increased from 7.15 tons in 1973 to 7.87 tons in 1974. The continued rise in the productivity rate was due to increased surface mining. Two fatalities occurred in 1974 (1 in 1973), and there were 262 nonfatal injuries (370 in 1973).

The Bureau of Mines publishes a series of weekly and monthly reports containing estimates of production derived primarily from factors based on carloading data furnished by the railroads and monthly truck shipments provided by the Commonwealth of Pennsylvania. The weekly and monthly estimates have been adjusted to the production total for 1974 and are presented on tables 13 and 14.

Legislation and Government Programs.—State and Federal Government programs in the environmental area continued throughout 1974, and included control and extinguishment of fires in abandoned underground and surface mines, prevention of surface subsidence above abandoned mines, reclamation of old strip pits and culm banks, and mine-water control projects designed to secure the safety of mine personnel and to protect anthracite reserves from the hazards of adjoining abandoned mine pools and possible inundation by surface flood waters.

Hydrologic studies were continued to evaluate mine-water problems. These involved determination of the varying heights of underground mine pools, their hydrostatic pressures and possible effect upon barrier pillars and mine dams protecting active mining operations, and acid mine-water drainage into surface streams and the unconsolidated valley fill. Under the closely related mine-water control program, a comprehensive series of mine pool monitoring stations have been installed, and additional phases of the project are proceeding in the Western, Middle, and Southern fields.

An overall program aimed at controlling fires in anthracite and other coal refuse banks continued in 1974. Efforts included investigations into the causes and environmental effects of these fires, attempts at their early detection and inventorying, and development of economic techniques for quenching and removing burning coal refuse banks.

Projects involving the reclamation of abandoned mine sites have been successful with the demonstration of different techniques. One project, completed in 1974, concluded that a mixture of anthracite fly ash, limestone, and fertilizer, spread and blended into the bank and then seeded with grasses and legumes, is successful and can be applied to other areas for reclamation.

The value of the longstanding map folio program to the public was demonstrated by the numerous requests received by the Bureau of Mines from various local authorities to evaluate subsurface conditions in relation to subsidence potential at proposed civic improvement sites, and possible structural failure in bridges and highways. Work continued on compiling surface and bed maps in stratigraphic sequence for selected areas.

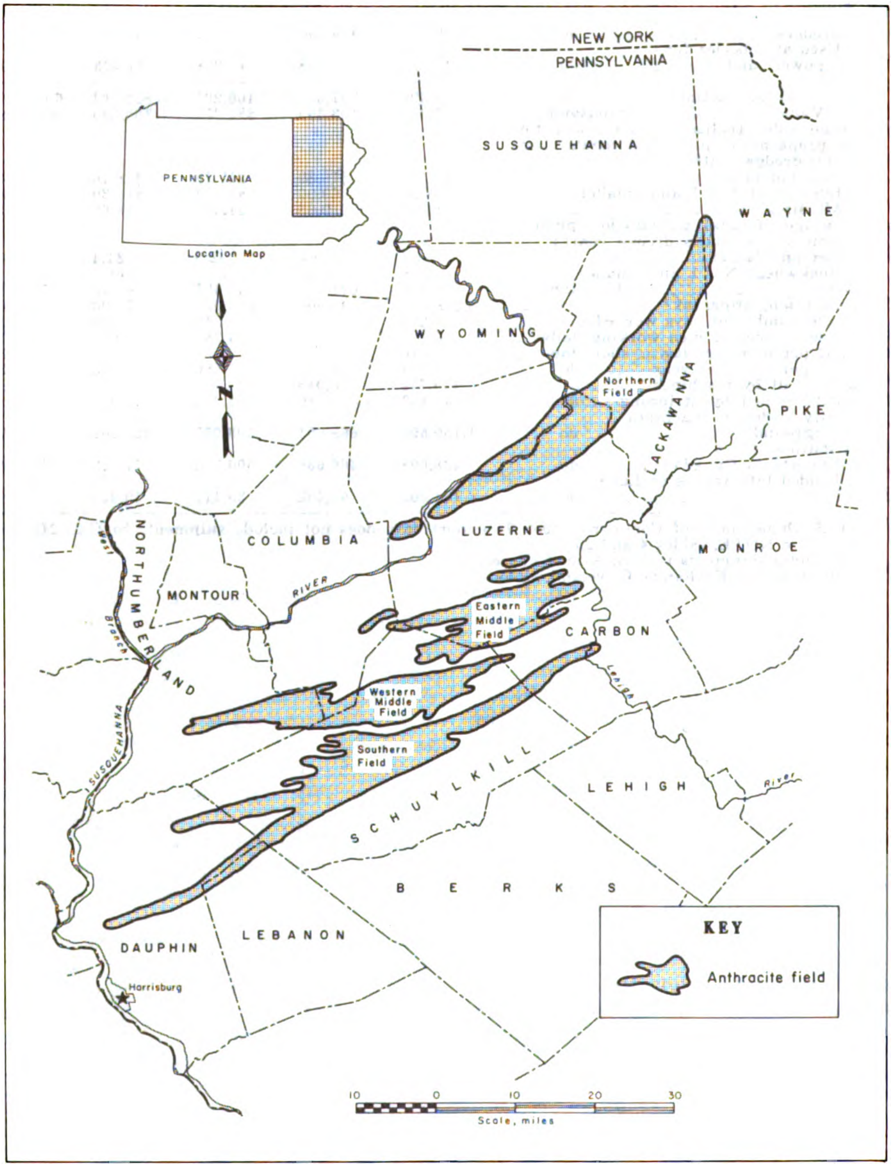

Figure 1.—Coalfields, regions, and counties of the Pennsylvania anthracite area.

DOMESTIC PRODUCTION

Production of Pennsylvania anthracite totaled 6.6 million tons in 1974, a decrease of 3% from that of 1973. Except for culm and silt recovery, all sources registered declines, ranging from approximately 9% for underground production to 66% for dredging operations. Underground production, which accounted for approximately 10% of the total output, continued its decline because of stringent and costly health and safety regulations, manpower shortages, and the high cost of pumping water from flooded mines. The output from underground mines in 1974 totaled approximately 657,000 tons, a decrease of 9% from that of 1973. The Schuylkill region accounted for 95% of the output, and the Wyoming region for the remainder. Strip pits accounted for 43% of the production (48% in 1973), culm and silt recovery for 45% (35% in 1973), and river coal for 2% (6% in 1973).

Two of the producing regions indicated losses in 1974. In the Lehigh region, total production was 6% less in 1974 because a 3% increase in production from strip pits was offset by a decrease of 23% in the recovery from culm banks. Production in the Wyoming region dropped 33% from that of 1973. The suspension of operations by a major coal company in the first half of the year inactivated the largest underground mine and strip operations in that region. Consequently, the underground output decreased by 80% and strip production by 70% from that of 1973. The bulk of the output was recovered from culm banks, which increased from 161,000 tons in 1973 to approximately 435,000 tons in 1974.

The Schuylkill region increased production 6% in 1974. The output from underground mines increased 12%; strip pits, 2%; culm and silt recovery, 26%; however, the recovery of river coal dropped approximately 66% in 1974.

Production of anthracite from strip mines totaled 2.8 million tons, a decrease of 13% from that of 1973. Production in the Schuylkill region totaled 1.5 million tons, an increase of 2%; the Lehigh region yielded 1.2 million tons, an increase of 3%; and in the Wyoming region, strip production totaled 208,000 tons, a 70% decline from that of 1973.

Culm and silt recovery totaled 2.9 million tons, an increase of approximately 556,000 tons, or 23% above the 1973 output. The Schuylkill region indicated a slight increase providing 69% of the total recovered in 1974, compared with 68% in 1973. The Wyoming region provided 15% of the total (7% in 1973); and the Lehigh region recovered approximately 16% of the total (26% in 1973).

Dredging operations produced about 150,000 tons in 1974, compared with 441,000 tons in 1973, a drop of 66%. Several operations were discontinued because insufficient coal remained on the riverbed to make the salvage operations economically feasible.

Mechanical loading of underground anthracite in 1974 declined 27% from the 1973 level, with a concurrent decrease of 10% in the loading units. Of the total underground output, 47% was loaded mechanically, compared with 58% in 1973. In operation were approximately 64 scraper loaders, 6 mobile loaders, and 41 conveyor and pit-car loaders.

Equipment used in the stripping operations and culm recovery consisted of 146 front-end loaders, 43 power shovels, and 105 draglines, a decrease of 2% from that of 1973.

The three leading counties in the production of anthracite were Schuylkill County, with a total of 3.1 million tons; Luzerne County, 1.5 million tons; and Northumberland County, 1.2 million tons. Other counties producing anthracite were Berks, Carbon, Columbia, Dauphin, Lackawanna, Snyder, Sullivan, and Susquehanna.

DISTRIBUTION

Reports submitted voluntarily to the Bureau of Mines by producers, wholesalers, and exporting firms indicated that 6,236,231 tons of Pennsylvania anthracite (a decrease of 2% from that of 1973) was shipped during the 1974 calendar year. Where possible, coal used largely for generating electricity and colliery fuel was eliminated from the statistics. Of the total shipped to market during the year, 81% was destined to points in the United States (a decrease of 2%), exports to Canada totaled 8% (an increase of approximately 1%), and 11% was exported to countries other than Canada.

In the United States market, shipments of pea and larger sizes declined 13%, but the buckwheat No. 1 and smaller sizes increased 2%. Canadian receipts of the pea and larger sizes decreased 16%, but the buckwheat No. 1 and smaller sizes, increased 4%. Exports to countries other than Canada indicated a decrease of 3% in the pea and larger sizes; however, the buckwheat No. 1 and smaller sizes increased 8% above that of 1973.

Shipments to the New England States totaled 53,796 tons, a decrease of 8% from that of 1973; to the Middle Atlantic States, 4,140,808 tons, a decrease of 4%; and to the Lake States, 349,165 tons, a decrease of less than 1%. However, the South Atlantic States and the "Other States" indicated increases of 6% and 12%, respectively, over that of 1973.

Of the total anthracite distributed, 3,594,337 tons was shipped by truck, and the remainder by rail.

Additional details of anthracite distribution for 1974 are presented in a Bureau of Mines report.[2]

CONSUMPTION AND USES

Apparent consumption of Pennsylvania anthracite in the United States in 1974, calculated as production minus exports, including shipments to the U.S. Armed Forces in West Germany, totaled 5.4 million short tons, compared with 5.7 million tons in 1973, a decrease of 4%. Consumption of anthracite in space heating declined 12% from that of 1973. The decline was due in part to the shortage of domestic sizes when a major coal company suspended operations in the first half of the year. Electric utilities consumed 1,498,000 tons of anthracite, an increase of 4% over that of 1973. Although the steel industry indicated a decline of 5% in the coke making category, the consumption of anthracite for sintering and pelletizing increased 59% over that of 1973.

Overall consumption of anthracite in 1974 was as follows: Space heating, 47% (51% in 1973); electric utilities, 28% (25% in 1973); coke making, 8% (8% in 1973); and sintering and pelletizing, 7% (4% in 1973); the remaining 10% was distributed among cement plants, colliery fuel, and other uses.

STOCKS

Monthly data on stocks held at retail dealers' yards indicated an inventory of 91,000 tons at yearend 1974, a decrease of 14% from that of yearend 1973. Electric utilities reported a decrease of 13% in inventories—930,000 tons at yearend 1974, compared with 1,066,000 tons at the end of 1973. Stocks at coke plants totaled 172,000 tons at yearend 1974, an increase of 77% over the 97,000 tons at yearend 1973. Stocks at Upper Lake docks (Lake Superior and Lake Michigan) comprised less than 500 tons at yearend 1974, relatively comparable to those of yearend 1973.

PRICES AND SPECIFICATIONS

Based on total production including colliery fuel and dredge coal, the average value per ton for 1974 was $21.87 f.o.b. preparation plant, compared with $13.22 per ton in 1973, an increase of 65%. The average value per ton of the larger sized groups was $30.41 f.o.b. preparation plant, an increase of $11.65 from that recorded in 1973. The prices for individual sizes (excluding dredge coal) were as follows: Egg, $32.91 (an increase of $13.35); stove, $31.54 (an increase of $12.03); chestnut, $31.06 (an increase of $11.76); and pea, $27.61 (an increase of $10.63).

The average value of the smaller sized

---

[2] U.S. Bureau of Mines. "Distribution of Pennsylvania Anthracite For The Calendar Year, 1974." Mineral Industry Surveys, Oct. 6, 1975, 8 pp.

groups was $18.88 per ton f.o.b. preparation plant, compared with $11.30 in 1973. The individual prices for the smaller sized groups were buckwheat No. 1, $28.36 (an increase of $11.75); buckwheat No. 2 (rice), $26.73 (an increase of $9.96); buckwheat No. 3 (barley), $23.16 (an increase of $9.04); buckwheat No. 4, $19.35 (an increase of $8.57); buckwheat No. 5, $18.82 (an increase of $10.42); and the "Other" category, $8.77 (an increase of $2.99).

Production of domestic sizes indicated a drop of 29% in 1974; however, the industrial sizes increased from 69% of the total in 1973 to 71% in 1974.

Average wholesale prices as quoted in the Black Diamond magazine f.o.b. preparation plant were as follows: Egg and stove, $22.50 to $42.50; chestnut, $21.75 to $42.75; pea, $19.50 to $37.50; buckwheat No. 1, $19.50 to $37.50; buckwheat No. 2, $19.50 to $37.50 and buckwheat No. 3 (barley), $18.50 to $36.50.

FOREIGN TRADE

According to data released by the U.S. Bureau of the Census, 735,173 short tons of Pennsylvania anthracite was exported in 1974, an increase of approximately 3% above that shipped in 1973. Of that total, 65% was exported to Canada, an increase of 1% over that in 1973; 27% to Europe; and the remainder to other countries. Exports to South America and to Asia decreased 72% and 26%, respectively. Among the European countries, shipments to France increased 57% over those of 1973, but exports to the Netherlands, Sweden, and Italy declined 71%, 66%, and 34%, respectively.

Census export data in table 25 indicate that approximately 199,000 tons of anthracite was shipped to Europe in 1974. However, these figures do not include anthracite shipped abroad for the use of U.S. Armed Forces in West Germany. Therefore, a more accurate measurement of exports can be obtained by adding the military tonnage (approximately 434,000 tons) to the tonnage reported by the Bureau of the Census. Consequently, a total of 1,169,000 tons of anthracite was exported in 1974.

WORLD REVIEW

World production in 1974 totaled approximately 206 million short tons, an increase of 6% over the revised total of 194 million tons in 1973. The combined production of the U.S.S.R., North Korea, and the People's Republic of China totaled approximately 152 million tons, or 73% of the total world production. The U.S.S.R., North Korea and the People's Republic of China had production increases of 3%, 10%, and 27%, respectively. Other countries registering increases in 1974 were Ireland, 27%; Romania, 37%; and West Germany, 2%. Declines were indicated in Belgium, 19%; Bulgaria, 8%; France, 16%; the Netherlands, 55%; Spain, 2%; and the United Kingdom, 11%.

Imports of anthracite into Japan in 1974 totaled 1.6 million short tons, or an increase of 5% over that of 1973. The principal sources were North Vietnam, 732,386 short tons; the People's Republic of China, 404,385 tons; and North Korea, 260,987 tons. The remainder, in descending order, was imported from Canada, the U.S.S.R., the Republic of South Africa, the Republic of Korea, South Vietnam, and the United States. Gas plants consumed approximately 83,000 short tons; coke plants, 159,000 tons; chemical plants, 93,000 tons; briquet plants, 925,000 tons; and 418,000 tons was consumed for other industrial uses.

Production of anthracite in the Republic of Korea totaled approximately 17 million short tons in 1974, an increase of 12% over that of 1973. An anthracite seam has been discovered in the Unsong area in Kyongsank Pukto (Province), with estimated reserves of 1 million tons. Most of Korea's present reserves are anthracite. Currently more than 90% of the anthracite production is consumed as domestic heating fuel. The South Korean Government, in a move to boost production and reduce domestic consumption, has raised the price

38%. Recent developments in world energy markets have resulted in the increased value of domestically produced anthracite in direct proportion to the rising price of crude oil.

North Vietnam produced 4 million tons of anthracite in 1974, an increase of 33% over that of 1973. Coal is North Vietnam's most important mineral with respect to value in foreign trade. The largest deposit, the Quang-Yen basin, forms a shallow arc extending approximately 95 miles from Sept Pagodas in the west to Tien Yen in the east, and further extends to Ke-bao Island. The deposit is predominately anthracite, with small amounts of other rank coals.

Production of anthracite in Spain totaled 3 million short tons in 1974, a decrease of 2% from that in 1973. During the first 9 months of 1974, imports totaled 6,264 short tons, a 36% decline from the same period in 1973. However, in the same period of time, exports increased from 5,467 tons in 1973 to 58,352 tons in 1974.

The U.S.S.R.'s production of anthracite in 1974 was approximately 87 million short tons, an increase of 3% over that in 1973. Of the 5 million tons exported, 1,268,000 short tons was shipped to France, 172,000 tons to Italy, 29,762 tons to Austria, and the remainder to other countries.

TECHNOLOGY

The Federal Bureau of Mines is currently investigating a process of selective flocculation as a possible means of recovering ultrafine coal particles from slimes. Such slimes remain substantially unaffected by conventional coal-washing methods and are discarded. This results in the loss of a valuable resource and generates water pollution and solid-waste-disposal problems.

Flocculation is the coalescence of minute particles into larger aggregates. Traditionally, the principal objectives have been to increase settling rates and to improve filtration and centrifugation characteristics. "Selective flocculation," as the term implies, refers to the agglomeration of one component of an admixture, the other remaining dispersed. Accomplishing this depends essentially on finding a flocculant that is preferentially adsorbed on one component under a given set of conditions.

Development of selective flocculation technology is presently aimed in several directions. In line with common coal-cleaning practices, attempts are being made to separate clean coal from the associated high-ash refuse. In addition, efforts will be made to separate or concentrate various petrographic constituents of clean coal. An application of the latter technique would be, for example, to reduce the concentration of fusain, which is inert in coking operations and in liquefaction processes.

The Bureau of Mines initiated a series of subsidence control projects and successfully demonstrated that surface stability over mined areas can be achieved.[8]

Many abandoned mine openings are inaccessible because of flooding or extensive caving. Such openings must be flushed blindly. A new technique for blind flushing inaccessible mine workings has recently been developed. This technique differs from the open gravity-feed methods previously described in that energy is used to achieve a dynamic suspension of solid particles, and the system is completely closed from the point of slurry mixing to the bottom of the injection hole.

In the pumped-slurry process, granular material is blended with water, and the suspension (slurry) is pumped to the point of deposition. Water from an inundated mine may be used and recirculated, or water from an external source may be used without being recirculated. During mixing, each solid particle becomes enclosed by fluid so that friction during transit is reduced. The slurry is pumped continuously from the mixing tank through a pipeline on the surface, then down through a borehole to the mine opening. The energy provided by the pump and the static head in the borehole give the velocity required to keep the solid particles in suspension and to transport them.

The completeness of filling in the open spaces is responsive to alterations in the velocity of flow, which changes with the growth of the mound of deposited solids. As the slurry first enters the open space from the injection hole, its velocity drops rapidly, solid particles settle out near the borehole, forming a doughnut-shaped mound on the mine floor. As the height of the mound approaches the mine roof, the velocity of the slurry increases through the narrowing channel, and solid particles are transported to the outer limit of the mound. Here the velocity decreases abruptly and solids are deposited. This type of deposition continues, and the mound of deposited fill builds outward. As resistance to flow of the slurry develops in one direction, a new channel is formed in another direction along a line of less resistance. Eventually nearly all mine openings are filled. The lateral extent of the fill is determined largely by the available energy in the system. As the mound of fill material builds outward into the mine, the flow channels between the mound and the mine roof become longer and resistance to flow increases. When this resistance, combined with resistance in the pipe, becomes great enough to reduce the velocity of the slurry below that required to transport the solid particles, transportation of the particles ceases. The particles then settle out, and the passage becomes filled.

---

[8] Whaite, R. H., and A. S. Allen. Pumped-Slurry Backfilling of Inaccessible Mine Workings for Subsidence Control. BuMines IC 8667, 1975, pp. 6–8.

The pumped-slurry method of blind flushing has the following advantages over the open gravity-feed method previously used:

1. Greater reduction in the number of injection bore-holes required. A single injection hole serves the purpose of many injection holes in the gravity-feed method.
2. More complete vertical filling of mine openings.
3. More complete areal coverage. Areas inaccessible because of surface improvements can be filled.
4. Less disruption of the community in the form of noise, dust, and traffic interference by drilling operations and trucking of fill material.

Table 2.—Standard anthracite specifications approved and adopted by the Anthracite Committee, effective July 28, 1947

Size	Round test mesh (inches)	Percent

[1] When slate content in sizes from broken to chestnut, inclusive, is less than the above standards, bone content may be increased 1½ times the decrease in slate content under the allowable limits, but slate content specified above shall not be exceeded in any event.

A tolerance of 1% is allowed on maximum percentage of undersize and maximum percentage of ash content.

Maximum percentage of undersize is applicable only to anthracite as it is produced at preparation plant.

Slate is defined as any material that has less than 40% fixed carbon.

Bone is defined as any material that has 40% or more, but less than 75%, fixed carbon.

[2] Ash determinations are on a dry basis.

[r] Revised.
[1] Furnished by initial carriers.
[2] Pennsylvania Department of Mines and Mineral Industries.
[3] Association of American Railroads.
[4] Ore and Coal Exchange, Cleveland, Ohio.
[5] Data furnished by Lake dock operators.
[6] Less than ½ unit.
[7] U.S. Department of Commerce. Does not include shipments to the U.S. military forces.
[8] Federal Power Commission.
[9] Estimated from reports submitted by a selected list of retail dealers located outside the producing region.
[10] Furnished by the Bureau of Labor Statistics from data obtained from authorized trade publications.

NOTE.—According to the Association of American railroads, 589,714 short tons of anthracite was exported to Europe during 1974 compared with 659,516 short tons for 1973. Of this total, 412,611 short tons was consigned to West Germany and the Netherlands, including exports to the U.S. military forces. This compares with 436,507 short tons for 1973.

Scranton, Hill section.	Filling abandoned mine voids	do	Do.
Carbondale West	Appalachian subsidence control, Project 8.	do	Do.
UNDERGROUND MINE FIRES			
Columbia County:			
Centralia Borough	Appalachia mine fire control, which includes Phase I exploratory drilling, Phase II (1) underground barrier pillars formed by injecting fly ash into mine void of west barrier, and Phase II (2) underground barrier pillars formed by injecting fly ash into mine void east barrier.	do	Work completed in 1974.
Lackawanna County: Eddy Creek, Boroughs of Throop and Olyphant.	Mine fire control—using a pumped slurry backfilling method of burned breakers refuse material.	do	Work started 1974.
SURFACE MINE RECLAMATION PROJECTS			
Lackawanna County:			
Scranton, Cedar Avenue.	Revegetation project of barren mine lands research demonstration.	do	Work started 1974.
Scranton, Taylor Borough.	Keyser Valley strip mine area reclamation demonstration project, Part III.	do	Work in progress 1974.
Luzerne County: Preston	Conservation and Development-Refuse bank reclamation demonstration project on the feasibility of using anthracite fly ash as a soil amendment together with lime, grass seeds, and legumes to vegetate the surface. Project is under the direction of the Energy Research Center at Morgantown, W. Va.	do	Started 1973. Still in progress.

27	146	Sept. 7	97	Total	6,617
May 4	143	14	134		
11	157	21	115		

[1] Estimated from weekly carloadings as reported by the Association of American Railroads and other factors; adjusted to annual production from Bureau of Mines canvass.

[2] Figures represent production in that part of week included in calendar year shown.

Table 14.—Estimated monthly production of Pennsylvania anthracite[1]

(Thousand short tons)

Month	1970	1971	1972	1973	1974
January	808	725	583	522	516
February	770	654	542	568	458
March	814	780	622	641	531
April	759	795	487	581	563
May	763	782	706	641	589
June	809	740	515	609	505
July	707	620	465	434	443
August	898	813	688	587	620
September	880	767	611	532	516
October	895	710	682	614	641
November	815	685	650	582	610
December	811	656	555	519	625
Total	9,729	8,727	7,106	6,830	6,617

[1] Production is estimated from weekly carloadings, as reported by the Association of American Railroads, and includes mine fuel, coal sold locally, and dredge coal.

Table 15.—Pennsylvania anthracite loaded mechanically underground

(Thousand short tons)

Year	Scraper loaders		Mobile loaders		Conveyor and pit-car loaders		Total loaded mechanically[1]	
	Number of units	Quantity loaded	Number of units	Quantity loaded	Number of units	Quantity loaded	Number of units	Quantity loaded
1970	103	491	20	183	147	476	270	1,151
1971	95	319	18	151	91	199	204	670
1972	81	347	16	136	46	111	143	594
1973	72	220	4	106	47	96	123	421
1974	64	89	6	169	41	49	111	307

[1] Data may not add to totals shown because of independent rounding.

Table 16.—Trends in mechanical loading,[1] hand loading, and stripping of Pennsylvania anthracite

(Thousand short tons)

Year	Fresh-mined coal							
	Underground					Strip pits		
	Mechanical loading	Percent of total underground	Hand loading	Percent of total underground	Total	Quantity	Percent of fresh mined coal	Total
1970	1,151	66.1	591	33.9	1,742	4,541	72.3	6,283
1971	670	52.1	617	47.9	1,287	4,478	77.7	5,765
1972	594	62.9	350	37.1	944	3,483	78.7	4,427
1973	421	58.0	305	42.0	726	3,279	81.9	4,005
1974	307	46.8	350	53.2	657	2,869	81.4	3,526

[1] Mechanical loading includes coal handled on pit-car loaders and hand-loaded face conveyors.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] An unspecified amount of semianthracite is included in figures for some countries.

[2] In addition to the countries listed, Canada, Colombia, New Zealand, and South Vietnam produce anthracite, but the level of production is not recorded, and available information is inadequate to make reliable estimates; in Colombia output may total 100,000 tons annually; in New Zealand and South Vietnam output is insignificant.

Cobalt

By Scott F. Sibley[1]

Demand for cobalt was relatively high during most of 1974, but began to slacken during the last quarter in line with general industrial activity. Cobalt-bearing salts and driers, magnetic materials, and superalloys were in greatest demand during the year. Consumer stocks at yearend were slightly below their 1973 yearend level. Government releases of cobalt from the strategic stockpile were again a significant source of supply during 1974, with over 8.5 million pounds released.

Legislation and Government Programs.—The General Services Administration (GSA) continued to offer specification-grade cobalt metal in various forms for sale during 1974. Sales were on an unrestricted-bid basis except that total sales of specification-grade material were limited to about 1 million pounds per month and 500,000 pounds per bidder per month. The stockpile objective for cobalt remained at 11,945,000 pounds in 1974. As of December 31, 1974, total U.S. Government stockpile inventory was 53,994,682 pounds of specification-grade cobalt. Government sales of cobalt for the year totaled 8,649,811 pounds, compared with 7,500,589 pounds in 1973.

DOMESTIC PRODUCTION

There was no domestic mine production of cobalt in 1974. However, Amax Nickel, Inc. completed renovation of its nickel-cobalt refinery, at Port Nickel, La. The plant became operational in late 1974 and was expected to produce about 1.2 million pounds of cobalt annually for markets in the United States and Europe. Botswana and other foreign sources will supply the refinery with a nickel-copper matte. Capacity was reported at 5 million pounds of cobalt per year.

A Tenneco Inc., subsidiary, Deep Sea Ventures, Inc. of Gloucester Point, Va., and three Japanese trading firms signed an agreement to evaluate and develop a Pacific Ocean site in order to mine cobalt-bearing manganese nodules from the sea floor. A similar venture was announced in February by a multinational consortium which included Kennecott Copper Corp. (KCC). The Tenneco project in its initial 3-year phase would cost an estimated $20 million; up to $200 million could be expended if the project were considered economically feasible and ores were marketed. Recovery of nodules from depths in excess of 2.5 miles would be made by Deep Sea Ventures.

CONSUMPTION AND USES

Consumption of cobalt in the United States in 1974 was 18.9 million pounds, 0.6% above that of 1973. The decline in the rate of consumption was a direct result of a general slackening of industrial activity throughout the economy. The pattern of cobalt consumption was little changed from that of 1973, with major consumption occurring in salts and driers, magnetic materials, superalloys, and cutting and wear-resistant materials. Consumption of cobalt in catalysts again registered a marked increase. Data reported by consumers showed that of the cobalt consumed in the United States in 1974, 77% was as metal, 19% was as salts and driers, 3% was as oxide, and 1% was as purchased scrap.

The market for rare-earth cobalt magnets expanded in 1974 and competed with conventional Alnico magnets in certain applications. Raytheon Co. manufactured a new samarium-cobalt alloy which, once magnetized, reportedly will hold its magnetism even though exposed to extremely high demagnetizing fields. According to company officials, diverse and complex shapes may be readily produced by the company's sintering method, thus limiting the amount of machining required. The magnetized material was reported to have an intrinsic coercive force greater than that of any other material available (1974).[2] To handle increased production of samarium and other rare-earth cobalt magnets, Raytheon reportedly installed a large sintering furnace at its Waltham, Mass., facility.[3] General Electric Research and Development Center developed and tested prototypes of what was reportedly the world's first bearingless aircraft tachometer generator. The generator contained a cobalt-samarium permanent magnet with a reported maximum energy product of over 25 million gauss-oersteds.[4]

Hitachi Metals, Ltd. introduced a new alloy termed "H-Aloy." This new corrosion- and wear-resistant cobalt-base alloy reportedly joins with the metal being coated in the centrifugal casting process to form a bimetallic coating with an average Shore hardness of 70 to 80. The patented material reportedly can be used for plastics injection molding, extrusion machinery, reciprocative pump machinery and cylinders, and oil drilling equipment.[5]

One innovative application for cobalt was a diverter valve part for auto emission systems in 1975 cars. The part is made of Dupont Tribaloy 480, which is 62% cobalt and can withstand temperatures of at least 1,500° F. However, the quantity used was only about 20 grams per car, totaling 20,000 to 25,000 pounds in 1975 cars.[6]

New Jersey Zinc Co. developed a new cobalt-brass alloy powder that was reportedly an improvement over conventional 70–30 leaded brass powder. According to company officials, fabricators can now attain ultimate tensile strengths up to 43,500 pounds per square inch, yield strengths of 33,200 pounds per square inch, and hardness of 100 R_h. Parts made from the new powder also undergo less dimensional change.[7]

The cemented carbide industry reportedly experienced a 15% to 20% growth rate during the year. Significant gains were recorded in cobalt-bearing wear-resistant components, cutting and metalworking tools, and mining and construction equipment.

PRICES

The producer price of $3.10 per pound for cobalt metal granules (shot) or broken cathodes in 551-pound (250-kilogram) drums was increased to $3.45 per pound on May 16, and to $3.75 per pound on July 8. The price remained at that level until January 23, 1975, when it was raised again, to $4.00 per pound, f.o.b. New York or Chicago. A weighted average price for the year was calculated to be $3.46 per pound of cobalt.

Sales of cobalt metal by the Government on a "sealed-bid" basis ranged in price from $2.745 to $3.611 per pound for specification-grade material. All prices were f.o.b. carrier's conveyance at Government storage locations.

FOREIGN TRADE

Exports of unwrought cobalt metal and alloys and of waste and scrap totaled 2,209,010 pounds, gross weight, having a value of $4,664,456, and went to 24 countries. West Germany and France received the greater part, with 1,286,088 pounds ($3,533,672) and 668,660 pounds ($1,747,303), respectively. Exports of wrought cobalt metal and alloys, 1,469,831 pounds, gross weight, having a value of $6,314,745, went to 16 countries. There were insignificant imports of salts and compounds in 1974.

WORLD REVIEW

Supplemented by U.S. Government stockpile releases, cobalt production in market economy countries was sufficient to meet demand in 1974. Zaire again led all countries in mine production of cobalt and accounted for 58% of the total world output. Cobalt production in 1974 increased in all major producing countries except Cuba and Finland, compared with that of 1973.

The United Nations Law of the Sea Conference was held in Caracas, Venezuela, in August. No treaty emerged from the meeting, which lasted 10 full weeks and was attended by representatives from 150 countries. Another conference was scheduled for Geneva in the spring of 1975. In spite of delays in obtaining a treaty, several companies and international consortiums were actively engaged in development and exploration of ocean floor mineral deposits. These included Kennecott Copper Corp.; Deep Sea Ventures; and International Nickel Co. of Canada, Ltd. (INCO). All three had invested more than $100 million in ocean mining technology. Countries involved in ocean mining included the United States, Canada, the United Kingdom, France, Japan, and West Germany. A joint company, Ocean Mining Associates, was formed to develop a 1.49 million tons-per-year (wet) manganese nodule mining operation over a 3-year period. A 37,200-square-mile area 1,000 miles off the tip of Baja California was expected to yield 2,767 tons per year of cobalt when mining equipment becomes fully operational.

Australia.—At Greenvale, late in 1974, Queensland Mines Limited began production of 650 tons per year of cobalt metal and 3,900 tons per year of mixed nickel-cobalt sulfides. The operation was a joint project of Metals Exploration Queensland Pty., Ltd., and Freeport Queensland Nickel, Inc. The laterite ore at the site was estimated to contain 45 million short tons of cobalt grading 0.12% cobalt.

Canada.—Production of cobalt in Canada totaled 4,240,000 pounds in 1974, up 27% over that of 1973. INCO was expected to negotiate labor contracts in 1975, but there was no indication of the position either side would take. Falconbridge Nickel Mines Ltd., which had planned to build a nickel-cobalt refinery at Becancour, Quebec, abandoned the project at least for the immediate future. The projected capacity of the refinery was to be 250 tons of cobalt per year. Mitsui Mining Co. and Copperfield Mining Co. were considering a cobalt-mining venture at Chicoutimi, Quebec. Mitsui was to provide the financing. Sherritt Gordon Mines Ltd., reportedly increased its imports of concentrates from Australia. The company also received concentrates from its Lynn Lake mine in Manitoba for processing at the Fort Saskatchewan refinery in Alberta.

Cuba.—Cuba planned to triple its nickel production by 1985, according to Angel Gomez Trubeda, Cuban Minister of Industrial Development. Presumably cobalt production would be increased as well, since Cuban ore also contains recoverable cobalt. Cuba produced about 3,600,000 pounds of cobalt in 1973, most of which was exported to the Soviet Union, Czechoslovakia, Romania, France, the United Kingdom, Italy, and Japan, with the Soviet Union receiving about 50% of the total.

India.—Work on India's first nickel-cobalt plant at Sukinda near Cuttack began in April 1974 and was scheduled for completion in 1978. The project was a joint venture of Orissa State and the Central Government and was estimated to cost $47 million. The deposits, located in the Sibunda Valley, were originally thought to contain 15 million tons of nickel ore. There were indications that the deposit might contain as much as 50 million tons of nickel-cobalt ore, which could mean an eventual production of 400 tons of cobalt per year.

Indonesia.—P.T. International Nickel Indonesia, a wholly owned subsidiary of INCO, proceeded with plans to produce a nickel-cobalt matte by 1976. At first a production of 16 million pounds per year of nickel with proportionate amounts of cobalt was expected. Plans being formulated in 1974 called for a severalfold increase in the original capacity.

Japan.—Japan took steps in 1974 to develop a refining capacity for cobalt. By mid-1975, about half of Japan's refined cobalt requirements reportedly will be met internally. Nippon Mining Co. was constructing facilities adjacent to its Hitachi plant and planned to produce about 1,300 short tons per year of cobalt from mixed sulfide ores of the Greenvale mine in Australia. Sumitomo Metal Mining Co. Ltd. planned to produce 1,600 tons per year of cobalt from its Niihama facility using mixed sulfides from the Philippines. According to reports, Sumitomo has already made test runs producing around 100 tons per year of cobalt.

Uganda.—Kilembe Copper Cobalt Ltd. continued work on a feasibility study for a cobalt extraction unit to be constructed at Lasese, Uganda, about 8 miles from the border with Zaire. According to company officials, preliminary data were being gathered in preparation for a detailed plant design. Production at Kilembe was severely hampered in 1973 because of a shortage of experienced supervisory and maintenance personnel.

Zaire.—Progress was made in 1974 toward construction of a 1,054 mile high voltage transmission line from the Inga Dam powerplant on the Congo River to Kolwezi in Shaba Province. A U.S. consortium, headed by Morrison-Knudsen Co., Inc., was awarded a $225 million contract for construction of the line. Scheduled for completion early in 1977, the power facility would have an ultimate capacity of 1,020-megawatts and allow further development of the vast resources of Shaba Province. Moreover, the transmission line will be tied in with an existing power generation and distribution network linked with nearby Zambia.

A principal beneficiary of the Inga-Shaba power project is the Société de Minière de Tenke Fungurume (SMTF), which is 20% owned by the Zaire Government. Others with interests in SMTF include Leon Tempelsman and Sons, Inc., of New York, Amoco Minerals Co. (United States), Mitsui Mining Co. (Japan), and two French groups, Bureau de Recherches Géologiques et Minières, and Omnium des Mines. SMTF owns a concession covering 577 square miles in Shaba Province. One feasibility study indicated reserves of 54 million tons of mixed sulfide ore grading 0.46% total cobalt. Processing facilities as well as a townsite were to be constructed at Fungurume, about 9 miles from Tenke, where the mining operations were to be established. Annual production of 6,000 tons of byproduct cobalt was anticipated when the facilities become operational. Cobalt production was to coincide with completion of the Inga-Shaba powerline in 1977. Fluor Utah Inc. of San Mateo, Calif., was awarded a contract for engineering of the ore processing facilities, from crushing through electrowinning, and was also to be responsible for procurement of equipment and construction. At yearend Fluor Utah had obtained complete financing for the $125 million of U.S. goods required for the project. The financing was obtained from SMTF, the Export Import Bank, and a consortium of banks led by Chase Manhattan Bank, New York.

An agreement was reached in April between the Zaire Government and the Belgian company Société Générale des Minerais (SGM), whereby the marketing and trading operations that SGM controlled were to be transferred to a Zairian firm. At the same time, an agreement was also reached on compensation by Zaire to SGM and associated companies for assets expropriated in 1967.

Générale des Carrière et des Mines (GECAMINES) embarked on an expansion program designed to increase its cobalt production by about 4,400 short tons by 1978. Zaire produced 19,340 short tons of cobalt in 1974. GECAMINES obtained a major loan at yearend to help finance the $435 million expansion of its copper and cobalt mining and refining capacity. The Libyan Arab Foreign Bank, European Investment Bank, and World Bank were to provide loans totaling $220 million; the balance was to be paid by GECAMINES itself. Plans for the project, located at Kolwezi in Central Shaba Province, included the development of two new open pit mines with attendant treatment facilities. These consisted of a concentrator, and a smelter and refinery of 100,000 tons' capacity each. In spite of these expansions, Zaire planned to hold production to about 17,000 short tons in 1975 and 1976 to avoid flooding the cobalt market. The ore extracted from the two new mines was to be processed in a DIMA concentrator. In addition, a flash smelting plant with ancillary cobalt treat-developments were part of GECAMINES' second 5-year expansion plan, which was to begin in 1975.

Zambia.—The Zambian Government obtained controlling interest (51%) in the country's major mining groups, Roan Consolidated Mines Ltd. (RCM) and Nchanga Consolidated Copper Mines Ltd. (NCCM). However, management and sales were left in private hands until contracts expire in 1979. Anglo American Corp. and American Metal Climax Inc. negotiated with the Zambian Government for the new articles of association, which were part of Zambia's general plan to assume management of its mining operations.

Exports from Zambia were shipped from the ports of Dar es Salaam in Tanganyika and Lobito in Angola, where the shipments reportedly were given priority. Zambia's border with Rhodesia remained closed during 1974.

Table 8.—Cobalt: World production by country
(Short tons)

Country	Mine output, metal content[1]			Metal[2]

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the countries listed, Bulgaria, Cyprus, East Germany, Greece, New Caledonia, Poland, Spain, Sweden, and Uganda are known to produce ores (copper, nickel, and/or pyrite) that contain recoverable quantities of cobalt, but available information is inadequate to make reliable estimates of output levels. Other nations may also produce cobalt as a byproduct component of ores and concentrates of other metals.

[2] In addition to the countries listed, the United Kingdom recovers cobalt metal from intermediate metallurgical products produced in Canada, but data on output are inseparable from the total reported by Canadian producers. Czechoslovakia presumably recovers cobalt from materials imported from Cuba, but data are inadequate to estimate output. Belgium and Japan, both of which import substantial quantities of crude materials containing cobalt, have not recorded output in recent years but are producing metal and/or cobalt compounds. Poland also apparently processes cobalt-bearing copper ores, but no data on cobalt recovery are available.

[3] Actual output not reported. Data presented for mine output are total cobalt content of all products, including nickel oxide sinter shipped to the United Kingdom for further processing and nickel-copper matte shipped to Norway for further processing. Data presented for metal output are total cobalt content of all products less cobalt output recorded for Norway. Thus, the metal data include cobalt content of oxides and other compounds that are not produced as metal and total metal output in the United Kingdom as well as actual metal output in Canada itself.

[4] Domestic mine output, if any, is negligible.

[5] Produced entirely from nickel-cobalt matte imported from Canada; domestic mine output is recovered abroad.

[6] Insufficient data are available to permit separate estimates for mine and metal production.

[7] Metal output, used in lieu of unreported mine production.

TECHNOLOGY

Bureau of Mines research dealing with cobalt focused on three areas in 1974: Extraction of cobalt from land-based sources; extraction from cobalt-bearing seabed manganese nodules; and rare earth-cobalt magnets. Work was begun at yearend to recover cobalt from primary lead-zinc ores of Missouri, and research continued on the beneficiation of low-grade western laterites to extract cobalt and nickel. Development of a process for economically recovering manganese and associated valuable metals from calcareous Atlantic Ocean nodules of the Blake Plateau also took place. Rare earth-cobalt magnets made of praseodymium-cobalt or mischmetal-cobalt were tested by Bureau researchers. The objective was to develop with these alloys high-performance permanent magnets that could replace the more expensive samarium alloys being used commercially.

The International Workshop on Rare Earth-Cobalt Permanent Magnets, sponsored by the University of Dayton, School of Engineering, was held in October. Discussion topics included raw materials, magnet alloys, magnet manufacture, and device applications.

Many patents were issued in 1974 on all phases of mining activity related to cobalt, from chemical precipitation to alkaline and acid leaching to manganese nodule recovery and extraction of metal values. The greatest number of patents dealt with chemical precipitation and alkaline leaching. In one important area of research, INCO received a British patent (No. 1,359,395) on the extraction of nickel and cobalt values from laterite. By this patented process, ore is divided into limonitic and silicate fractions. The bulk of the nickel and cobalt content is then selectively reduced from the silicate fraction, and the limonitic fraction is pressure-leached with sulfuric acid to yield a leach solution containing nickel and cobalt. The selectively reduced silicate fraction is then mixed with the leach solution, and the resultant slurry is aerated, causing the reduced metal to react with free acid. A pregnant leach solution is produced which is suitable for treatment by conventional techniques.

Several companies experimented with techniques to mine and process cobalt-bearing manganese nodules from the ocean floor; two basic systems were tested. One system involved a sea floor dredge head, which sucks in water and nodules in a huge vacuum operation. The nodules are cleaned and crushed as they are sucked in and then lifted up a several-mile-long pipe to the mining ship. The other system was one in which a series of scoops or buckets are mounted on an extremely long loop of cable. The buckets are hauled to the ship in a continuous dredging process. Chemical processing of the nodules also received much attention. One company operated several pilot plants that used an ammonia leaching process, and one full-scale plant was being designed. Another company used a wet process treatment that reportedly recovered 95% of the metal in the nodules, producing pure sheets of cobalt and other metals. A full-scale operation of this type, designed to process 1 million tons of nodules per year, was anticipated.[8]

Research into high-temperature-resistant alloys by General Electric Co. constituted one possibly significant development. The material developed had the potential for replacing cobalt in certain applications. According to company officials, the silicon carbide composite, with the addition of 1% boron, combines the temperature and corrosion resistance of ceramics with the ductility and high fracture toughness of metals. Because the ceramic material can be cast into component shapes, expensive tooling and machining operations may be avoided.[9] Another superalloy was being developed by Battelle Memorial Institute. The new iron-based alloy contained 16% chrome and 2.6% yttrium oxide and reportedly could be used where currently (1974) only nickel-based and cobalt alloys would perform.[10] Technical papers were presented during 1974 on heat-resisting alloys and composites, cobalt alloy systems and phases, permanent to soft magnetic materials, films and coatings, tool and wear-resisting steels, and alloys and unalloyed coatings and compounds.[11]

Bureau of Mines scientists developed cobalt-molybdenum catalysts which demonstrated excellent activity in the desulfurization of high-sulfur bituminous coal and the hydrocracking of crude shale oil. Conversion of coal to gaseous or liquid fuel is another field in which the growth potential of cobalt-containing catalysts is considered great. In addition, fluidized coal combustion, coal gasification, coal liquefaction, and shale oil retorting facilities will require containment alloys that may be high in cobalt.

Coke and Coal Chemicals

By Franklin D. Cooper [1]

Production of coal coke in the United States in 1974 was 4.3% less than in 1973 because of a coal miners' strike late in the year and a 5.2% decrease in production of pig iron and ferroalloys in blast furnaces. Also contributing to the decrease was a 7.1% smaller demand for foundry coke, and a 24.7% decrease in tonnage of coke shipped to other industrial plants.

Production remained relatively stable throughout the year and averaged 5.13 million tons per month. The average daily output for all plants ranged from a low of 133,000 tons in December to a high of 179,900 tons in February. Average daily output for the year averaged 168,700 tons.

During July and throughout the fourth quarter, demand for coke exceeded production primarily because of interruptions in coal deliveries. Accordingly, producers' stocks of oven coke were 21% lower at the end of the year than 1 year earlier.

Blast furnaces continued to use the bulk of the Nation's coke production, receiving 91.6% of the 61.6 million tons of coke distributed by producers. However, consumption of coke per ton of hot metal produced at blast furnaces increased 18 pounds despite a net overall increase over 1973 in coke equivalent of fuels injected through blast furnace tuyeres, which amounted to 281,840 Btu or 21.7 pounds of coke equivalent per ton of hot metal.

Breeze production per ton of coal increased 8.5% (9 pounds) because of the use of some marginal-quality coking coals, the slightly reduced use of low-volatile coals in the mixtures carbonized, and generally longer coking time late in the year. Breeze is unsuitable for most metallurgical applications because of its small size and high-volatile and ash contents. The larger part of the breeze production was used by producers for sintering iron ores and for other industrial purposes. However, 45% of the output was sold, mainly for use as a reductant in electric furnaces producing elemental phosphorus. Tonnage of breeze sold was 6.7% more than in 1973 and brought an average of $17.83 per ton, up from $10.39 in 1973.

The average delivered value of all coals, including anthracite, carbonized in slot ovens, increased 97.1% and averaged $36.49 per ton. This increase was reflected directly in average coke prices, which increased 53% to $65.74 per ton. The largest price increase occurred in sales of coke to foundries. Foundry coke prices, which averaged $78.92 per ton, f.o.b. plant, were 44% higher than in 1973.

Production of tars, ammonia, light oil, and coke-oven gas decreased because less coal was carbonized.

Foreign trade was relatively active with coke exports at 1.28 million tons, about 2.1% of domestic production. The bulk of the exported coke was shipped to Canada, Mexico, and West Germany. Coke imports were 228% greater in 1974, but exports were down 8.4%.

The total value of all coals carbonized in slot ovens was $3,242 million, and the total value of all products of carbonization was $5,262 million. The combined value of coke and breeze, the principal products, accounted for 87.6% of the total value of all products.

---

COKE AND BREEZE

DOMESTIC PRODUCTION

A substantial decrease in the production of pig iron and ferroalloys in 1974 was accompanied by a 3.2% decrease in demand for blast-furnace coke. Output of oven coke plus beehive coke averaged 5.13 million tons per month, with 5.49 million tons produced in January and 4.13 million tons in December. Daily production for the year averaged 168,715 tons, down 4.3% from the average daily output of 1973.

Forty-eight furnace plants produced 91.6% of the oven coke. These plants, owned by or financially affiliated with iron and steel companies, were operated mainly to produce coke for use in iron blast furnaces. The remaining oven coke was produced by 14 merchant plants, a segment of the coke industry producing and selling blast furnace, foundry, and other grades of coke on the open market.

Coke was produced in 19 States in 1974. The relative amounts of coke produced in the various States have changed little in the past decade. Connecticut and Massachusetts have ceased to be producing States, and production was discontinued in New Jersey in 1971. Because coke is used principally for blast furnace fuel, the coke industry is concentrated in the major steel-producing areas of the Eastern and North Central States. The bulk of the 1974 coke output was produced in 14 States east of the Mississippi River. Five States west of the Mississippi River produced less than 7% of the total production. Pennsylvania, the largest producer, accounted for 27% of the output and was followed by Indiana and Ohio. The combined ouput of these three States was 56% of the national total.

An average of 1,366 pounds of breeze-free coke was produced for each ton of coal carbonized in the United States in 1974. The yield of coke from coal, which averaged 68.28%, has remained fairly constant during the past decade.

Table 1.—Salient coke statistics

	1970	1971	1972	1973	1974

r Revised.

[1] Data may not add to totals shown because of independent rounding.

The word breeze refers generally to coke particles, carbonized bony coal, and slaty rock passing through a ½-inch-square screen. Approximately 29% of the breeze produced in 1974 was used as a fuel in agglomerating plants. The remainder was sold mainly for use as a fuel for smelting phosphate rock to produce elemental phosphorus. The amount of breeze sold has increased significantly in recent years; about 45% of the quantity produced was sold in 1974.

The breeze yield per ton of coal carbonized is influenced by oven operating practices and the quality of the coals carbonized. The lowest yield equaling 3.6% was recorded for Pennsylvania; the yield for Indiana averaged 8.0%. The national average yield of 5.7% has not varied significantly during the past decade.

An average of 114.6 pounds of breeze was produced for each ton of coal carbonized at oven-coke plants. Breeze yields of beehive-coke plants were substantially higher than those of oven plants, but beehive breeze production was negligible because only a few plants had recovery facilities.

CONSUMPTION AND SALES

Apparent consumption of coke in the United States totaled 64.1 million tons. This quantity (domestic production plus imports, minus exports and changes in stocks) was 1.7 million tons less than that consumed in 1973. The decrease was attributed to smaller demand for blast-furnace coke, caused by a 5.3-million-ton decrease in blast-furnace pig iron and ferroalloys production.

The amount of coke required to produce 1 short ton of hot-metal ouput increased from 1,200 pounds in 1973 to 1,218 pounds in 1974.

Although a variety of operating practices affect blast-furnace coke rates, the increase in the 1974 coke rate resulted despite a 21.7-pound coke-equivalent increase of supplemental fuels injected through blast furnace tuyeres per ton of hot metal produced. The principal fuels used in blast furnaces to reduce coke consumption in 1974 were fuel oil, tar and pitch, and natural, coke oven, and blast furnace gases. Although the units of measurement differ, and the quantity of each fuel used varied greatly, the total calorific value of all supplemental fuels consumed in blast furnaces in 1974 was equivalent to approximately 5.3 million tons of coke. Oxygen consumption in blast furnaces equaled 25,813 million cubic feet, up 23% from the 1973 consumption. The use of oxygen reduces the blast-furnace coke requirement by making available more sensible heat during the reduction of iron ore to pig iron.

A total of 61.6 million tons of oven and beehive coke was sold and used for all purposes, of which 90% was oven coke supplied by furnace plants. The bulk of this coke was retained by producers for use in their own blast furnaces. Furnace plants sold about 1.9 million tons of coke, 28% of the total coke sold commercially. Fifty-nine percent of the furnace-plant sales was shipped to other blast-furnace plants.

Merchant plants distributed 5.1 million tons of coke, 97% of which was sold on the open market. Principal markets were blast-furnace operations without coke facilities, independent gray-iron foundries, nonferrous smelters, and chemical plants. About 3% of the merchant coke was used by its producers, principally in chemical plants and affiliated foundries.

One percent of the total coke distributed was supplied by beehive plants and was sold for blast-furnace use.

All States except Alaska and Hawaii, received shipments of coke and breeze in 1974. Alabama, Illinois, Indiana, Michigan, New York, Ohio, Pennsylvania, and West Virginia, which are the major iron- and steel-producing States, received 84% of the total coke and breeze distributed.

The bulk of the coke distributed was blast-furnace coke that was consumed within the producing State, as most blast furnaces were integrated with coke ovens. A few companies shipped coke to affiliated blast furnaces in other States.

About 5.5% of the breeze-free coke distributed was shipped to foundries. The chief recipients of foundry coke were the automotive, farm-machinery, machine-tool, heavy-machinery, railroad, and electrical-equipment industries. Most of these industries are concentrated in the East and Midwest. The combined consumption of Alabama, Illinois, Indiana, Michigan, New Jersey, New York, Ohio, Pennsylvania, and Wisconsin accounted for 74% of the foundry-coke shipments. Foundry coke also was consumed in 36 other States.

Coke used for miscellaneous applications was widely distributed, with 44 States receiving shipments of other industrial coke. The principal consumers were nonferrous smelters, alkali plants, and plants that manufacture calcium carbide and elemental phosphorus. Alabama, Idaho, Michigan, Ohio, Pennsylvania, and Utah received 51% of other industrial coke.

STOCKS

Yearend stocks of coke were 21% less than at yearend 1973 as the quantity of coke distributed exceeded production by about 1.1 million tons. Oven-coke plants ended the year with an average 4.7-day supply based on the December rate of production. Normally, beehive plants do not stock coke.

The bulk of the stock was at furnace plants, that had roughly a 6-day supply compared with a 2-day supply at merchant plants. There were no producers' stocks of beehive coke at the end of 1974.

Stocks of coke breeze at producers' plants increased 12% during 1974. Roughly, 72% of the breeze on hand was at furnace plants.

VALUE AND PRICE

The average value of receipts for all grades of oven coke reached $65.74, up $22.82 per ton, and beehive coke averaged $44.02, up $16.71 per ton. The 1974 values represented increases of 53% for oven coke and 61% for beehive coke.

For oven coke, an increase of 44% raised the average price of foundry sales to $78.92 per ton; commercial sales to blast-furnaces increased an average of 64% to $53.28 per ton. Oven coke used for other industrial purposes increased 62% in price to $59.33 per ton.

The differential between the average price of blast-furnace and foundry-oven coke is attributed to the tighter specifications for foundry coke that make it a more costly product and to its superior properties resulting from the long coking times at lower temperatures of coal mixtures containing up to 50 weight-percent low-volatile coal, and occasionally petroleum coke, anthracite, or pitch. The differences in the average values of oven and beehive cokes are partially due to the additional transportation costs of coal delivered to oven-coke plants, and the substantial investment and maintenance costs of slot-type ovens.

FOREIGN TRADE

Foreign trade in coke was relatively active. Exports at 1,277,681 tons amounted to 2.1% of production. Approximately 77% of the coke exported went to Canada, Mexico, and West Germany at an average value of $33.84 per short ton. Total exports averaged $34.09 per ton, up $10.33 per ton from $23.76 in 1973. Imports of coke at 3,540,326 tons far exceeded the 1,077,737 tons imported in 1973. The value of all coke imports in 1974 averaged $54.56 per ton compared with $36.43 per ton in 1973. West Germany and the United Kingdom furnished 88.8% of the imports at an average value of $54.31 per ton.

Canada remained the principal foreign market, receiving nearly 709,717 tons, or 55.6% of the foreign shipments. Other countries receiving substantial amounts of U.S. coke were West Germany, Mexico, the Netherlands, and Spain. Although coke was shipped to 23 countries in 1974, these four countries together with Canada received 92% of the total exports. Eighty-one percent of the total coke exported through 24 customs districts was shipped from the Baltimore, Buffalo, Detroit, Laredo, Norfolk, and Philadelphia customs districts.

Because of shortages of domestic coke, imports increased 228% above those of 1973. This was the largest quantity of coke imported in a single year to date.

COKING COALS

QUANTITY AND VALUE OF COAL CARBONIZED

A total of 89.8 million tons of bituminous coal was carbonized at high temperatures for the production of coke. This quantity, equaling 15% of the 1974 bituminous coal output of the United States, was the second-largest coal market. In addition to bituminous coal, 444,000 tons or approximately 7% of the U.S. anthracite production was used in coking-coal blends. Anthracite was used principally in the production of foundry coke to achieve greater size and density that are desirable properties in the melting of iron in foundry cupolas.

The delivered average value of all coal carbonized by oven-coke plants was $36.49 per ton. The average value of coal carbonized by beehive-coke plants cannot be published to protect confidentiality of the data. Varying percentages of the average value of coal shipped to oven-coke plants represent transportation costs that often exceed the value of the coal at the mine; this factor partially accounts for the high value of the coal consumed in some States.

The average value per ton of coals consumed for coke production at oven-coke plants was 99% greater than in 1973. Coals delivered to some States had increases in average value per ton ranging up to 108%. The highest coal price was recorded for Michigan where the delivered value of coals used for coke production by all plants averaged $44.29 per ton.

An overall average of 1.46 tons of coal, valued at $53.28, was required for each ton of oven coke produced. Beehive ovens required an average of 1.59 tons of coal per ton of coke output.

BLENDING

Blending of coals currently is standard practice at oven-coke plants because many individual coals when used alone do not produce satisfactory quality coke. Blending is performed to improve the chemical and physical properties of coke, to limit the expansion pressure developed on oven walls during carbonization, and to broaden the use of lower quality coals that could not be used alone for metallurgical-grade coke production. Standard oven coke for blast furnace use is made from mixes containing up to 25 or more weight-percent of low-volatile coals blended with medium- and high-volatile coals. High-volatile coals when used alone produce lower yields of weaker coke. Low-volatile coals when used with high-volatile coals improve the yield and the physical properties of the coke. The weight-percentages of low-volatile coals used are restricted because of their cost and their expansive behavior that damages oven walls. Some plants add medium-volatile coals or other materials to their blends of high- and low-volatile coals to replace the equivalent weight of a blend of low- and high-volatile coals; the use of anthracite imparts size and density to the coke; and the presence of tar pitch in the coal mix increases the strength of coke. Blending also permits the use of some high-sulfur-content coals with low-sulfur coals to produce a coal mix for producing high-quality coke with an acceptable sulfur content.

The overall percentages of high-, medium-, and low-volatile coals used in coke mixes have varied little in the past decade although there are wide variations in the proportions used by individual plants. West Virginia plants and those in the Western States used the largest percentages of high-volatile coals in their blends, but plants in Minnesota and Wisconsin used relatively high percentages of low-volatile coal. Compared with furnace plants, some merchant plants used approximately 50 weight-percent of low-volatile coal to produce strong foundry coke.

The types of coal used in each plant are determined by the availability of the desired coal; the quality of various coals including moisture and content and composition of ash, ash-fusion temperature, volatile content, expansive properties; cost of delivered coal; storage characteristics; and the physical and chemical properties of the final coke.

SOURCES OF COAL

Of the 25 States that produced bituminous coal in 1974, only 14 produced coal that was shipped to coke plants. Ten States supplied 87.7 million tons of coal for coking. The combined shipments from Arkansas, Maryland, Ohio, Tennessee totaled only 398,000 tons.

Thirty percent of the coals received by oven-coke plants was produced in West Virginia and 28% in Pennsylvania. West Virginia shipments comprised low-volatile coals from McDowell, Wyoming, and Raleigh Counties, and medium-volatile coals from Fayette, Logan, Mingo, and Nicholas Counties. Pennsylvania supplied high-volatile coals from Allegheny, Greene, and Washington Counties and low-volatile coals from Cambria and Somerset Counties. Pennsylvania and West Virginia coals were widely distributed and used in most of the coke-producing States.

Kentucky supplied 17% of the coal shipments to coke plants, all of which was high-volatile coal produced mainly in Floyd, Harlan, Letcher, and Pike Counties.

Illinois produced high-volatile coking coals mainly in Franklin and Jefferson Counties; other States with substantial production were Alabama, Colorado, Utah, and Virginia. Most of the coal produced in these States was used within the State. Colorado and Utah, however, supplied most of the coals that were carbonized in California.

CAPTIVE COAL

Approximately 52% of the coal received by oven-coke plants was produced by company-owned or affiliated mines. This captive coal, ordinarily, does not move in commercial channels. In 1974, 54% of the coal received by furnace plants was captive. Some merchant plants also owned coal mines, but only 22% of the coal received was captive production.

STOCKS

Stocks of bituminous coal at oven-coke plants remained fairly constant throughout the year, ranging from an average supply of 25 to 32 days at each plant. Bituminous stocks reached their highest yearly level during May when month-end quantities totaled 7.8 million tons. The lowest level, 6.0 million tons, was reported at the end of December.

Despite market competition for low-sulfur coals during the latter part of 1974, bituminous coal stocks at the end of 1974 were only 12% lower than when the year began. The 6.0 million tons on hand at all plants at yearend was equivalent to a 31-day supply at the December 1974 rate of consumption.

Stocks of anthracite at the end of 1974 totaled 172,000 tons, which was equal to a 141-day supply at the 1974 average rate of consumption.

COAL CHEMICALS

The term "coal chemicals" refers to the refined materials recovered from the crude liquids obtained from the gases and vapors released during coal carbonization. Three materials—ammonia, tar, and light oil—are normally recovered at oven-coke plants using condensation and absorption processes. The remaining noncondensible material, which is rich in hydrogen and methane, is called coke-oven gas. Except for ammonia, which is recovered as an aqueous solution or converted to ammonium sulfate or phosphate and sold as produced, the materials are, in most instances, further processed to yield a number of primary organic chemicals or chemical mixtures, the most important of which are benzene, toluene, xylene, solvent naphtha, crude chemical oil (often termed carbolic oil), and pitch. Although many oven-coke plants in the United States are equipped to process tar and light oil, the extent to which individual plants are utilized depends upon economic conditions and the general size of the plant because yields of the various chemicals are low.

Yields of chemicals vary with the kind of coals carbonized, carbonizing temperatures, and operating techniques and equipment, but approximately 315 pounds of coke-oven gas, 90 pounds of tar, 20 pounds of crude light oil, and 5 pounds of ammonia are recovered for each ton of coal carbonized. In standard units of measure, these quantities amount to about 10,500 cubic feet of coke-oven gas, 10 gallons of tar, and 3 gallons of crude light oil. Ammonia was recovered as ammonium sulfate at most coke plants at a yield averaging 17 pounds per ton of coal.

In terms of calorific value, the products, excluding coke, recovered by oven-coke plants in 1974 totaled 547 trillion Btu. This quantity was roughly equivalent to about 23% of the heating value of the coals carbonized.

Among the technological developments concerning coal chemicals, The Dow Chemical Co. of America reported that phenanthrene was easily separated from anthracene if the mixture was dissolved in ethanol or acetone. Using a process protected by U.S. Patent 3,793,387 (1974), phenanthrene was precipitated by the addition of water to give a 70% recovery.

According to the Great Lakes Carbon Corp., spinnable pitch may be produced by forming the pitch into particles smaller than 100 mesh before dissolving them in two stages, the second stage consisting of dissolving the undissolved material from the first stage. The process is protected by British Patent 1,352,625 (1974).

U.S. Patent 3,787,300 (1974) claims

that the life of molten cryolite cells for aluminum production can be prolonged by coating the anode and cathode with pitch mixtures.

West German Patent 2,300,023 (1973) disclosed a process for producing isotropic carbon from creosote oil and cracked petroleum distillates by treatment with air followed by carbonization at 1,000° C.

Tars resulting from the carbonization of bituminous coal containing added pitch were processed by a procedure giving improved heat balance and economy. A nonionic demulsifier used before distillation improved the gravity separation of water and thus decreased the load on the distillation column.[2]

Eight U.S. steel companies were building new coke batteries at yearend that were expected to increase the supplies of ammonium compounds and aromatics[3] as shown in the following tabulations:

Company	Location	Million tons per year	Start-up target date
Armco Steel Corp	Middletown, Ohio	[1]2.0	July 1976.
Bethlehem Steel Corp	Bethlehem, Pa	[1]1.3	Mid-1975.
Inland Steel Co	East Chicago, Ind	1.8	1978.
Jones & Laughlin Steel Corp	Aliquippa, Pa	1.5	Mid-1975.
	do	1.5	Not contracted.
Lykes-Youngtown Corp	Indiana Harbor, Ind	1.5	Mid-1977.
Republic Steel Corp	Cleveland, Ohio	0.4	1976.
	Warren, Ohio	0.8	1978.
United States Steel Corp	Gary, Ind	[1][2]1.25	Late 1975.
	do	[1][2]1.25	Late 1976.
Wheeling-Pittsburg Steel Corp	Follansbee, W. Va	1.5	Mid-1977.

[1] Estimated by Chemical Week.
[2] Minimum capacity.

Product		Present capacity[1]	Additional capacity by 1981[1]
Ammonia compounds[2]	thousand tons per year	700	125
Benzene	million gallons per year	180	25
Toluene	do	40	5
Xylenes	do	8	1
Phenol	million pounds per year	30	4
Naphthalene[3]	do	640	85
Cresols	do	100	9
Xylenols	do	35	3
Phenanthrene, anthracene, other cyclics	do	800	80

COKE-OVEN AMMONIA

Coal carbonized at high temperatures releases nitrogen and hydrogen, which combine to produce ammonia. Ammonia must be removed from the gas to reduce the subsequent formation of corrosive compounds with hydrogen sulfide and hydrogen cyanide. Coke plant operators normally recover ammonia as an aqueous solution, or as ammonium sulfate or phosphate. However, 14 plants did not recover ammonia as a salable product in 1974.

Production of ammonia decreased 9% because the number of recovery plants decreased by three. However, the average value per ton of both ammonium sulfate and ammonia liquor increased, as did the total value of sales. Ammonia products sold in 1974 represented 5.7% of the total value of all coal-chemicals sales.

COKE-OVEN GAS

Coke-oven gas, having a gross heating value usually ranging from 520 to 600 Btu per standard cubic foot, is principally used for heating coke ovens and steel- and allied plant furnaces. Small quantities are also sold for distribution through city mains and for other industrial uses. Gas yields vary among plants, but the average quantity of gas produced for each ton of coal carbonized in all slot ovens was 10,890 cubic feet, 1.6% more than the average yield of 10,720 cubic feet for 1973. However, total gas production decreased 2.8% because about 4.3% less tonnage of coal was carbonized in 1974.

Approximately 39.4% of the coke-oven gas produced was used for heating coke ovens. The remainder of the gas produced was used by producers to fuel boilers, transferred to steel or allied plants to heat open-hearth and other metallurgical furnaces, sold for industrial use, or distributed through city mains. A small part of the production was wasted when the gas was burned in the atmosphere in situations where production exceeded demand.

Although coke-oven gas was the principal fuel used for heating coke ovens in 1974, some operators used a mixture of coke-oven and blast-furnace gas, or a mixture of blast-furnace and natural gas for underfiring. A total of 416 billion cubic feet of coke-oven gas equivalent was so consumed, of which approximately 92% was coke-oven gas.

Surplus coke-oven gas used and sold in 1974 was valued at $299 million, a 57% increase above the 1973 value. No value was reported by producers for coke-oven gas used to heat coke ovens, but by applying the average value of $0.521 per thousand cubic feet reported for surplus gas to the gas used for underfiring, the total value of all coke-oven gas used and sold in 1974 would be $497 million. This amount is equivalent to 15.4% of the total value of the coal carbonized at oven-coke plants.

COAL TAR AND DERIVATIVES

All oven-coke plants produced tar in quantities varying between 6 and 9 gallons per ton of coal carbonized. Because the carbonization of high-volatile coals yields a larger yield of tar, coke plants in California, Colorado, and Utah using large percentages of high-volatile coals had the highest tar yields. Because 4.3% less coal was carbonized in oven-coke plants and the yield per ton of coal was down 3.4%, tar production was 7.5% less than in 1974. Both merchant and furnace plants had lower yields and also lower production.

Coke-plant operators consumed 54.6% of the crude tar produced. Of this quantity, 50% was processed (refined or topped) and 49% underwent no processing and was burned for fuel. The remaining production together with withdrawals from stock was sold to tar-distilling plants for refining into a variety of tar-derived products.

Most of the coke plants that processed crude tar in 1974 fractionated the tar in a process called "topping," whereby distillate fractions, consisting mainly of low-boiling tar acids and bases together with naphthalene, are obtained from the crude tar. The residue (called soft pitch) was usually used for fuel. Furnace plants integrated with steel plants in particular benefited from this operation because they could sell the distillate and retain the pitch for use as fuel, thereby reducing the amount of other fuels normally purchased. However, the relative quantities of tar topped, burned, or sold, depend on a number of economic factors, such as the availability and current market prices of tar, tar distillates, and other substitute fuels. Most of the merchant plant tar production was sold because these plants had little use for the pitch that represented 65 to 92 volume-percent of the crude tar feed to the topping stills.

The majority of the plants that processed crude tar recovered only crude chemical oil (also known as carbolic oil) and liquid residual tars ranging up to soft pitch. Some of the larger plants recovered a number of tar-based products, including creosote oil, cresylic acid, cresols, naphthalene, phenol, cresols, xylols, pyridine, quinoline, and medium and hard pitch. Although statistics on many of these tar derivatives are not shown in this report because of company confidentiality, the data were transmitted to the U.S. Tariff Commission, for publishing with similar data from tar distillers and petroleum refiners, in monthly and annual reports on synthetic organic chemicals.

CRUDE LIGHT OIL AND DERIVATIVES

Crude light oil is a mixture of aromatic hydrocarbons that are absorbed from the gas after tar, ammonia, and in some instances, naphthalene have been removed. Crude tar also contains an insignificant amount of light oil, but this usually is not recovered at coke plants. Virtually all crude light oil produced at coke plants is recovered by an absorption process in which the gas is contacted with a high-boiling petroleum oil or a coal-tar-based distillate as the gas passes through absorption equipment. Crude light oil is stripped from the absorption oil by direct steam distillation. Approximately 2.5 to 3.0 gallons of crude light oil (20 pounds) is recovered for each ton of coal carbonized. Yields vary with the kind of coals carbonized and with operating conditions. An average of 2.64 gallons of light oil per ton of coal carbonized was recovered at 51 plants that extracted light oil in 1974. Yields per ton of coal were about the same in both merchant and furnace plants as in 1973. Eleven plants left the light oil in the gas to increase its calorific value.

Producers sold 44% of their crude light oil output. The modest increase of crude light oil sales in recent years was attributed to the inability of some plants to produce derivatives meeting the rigid specifications of dependable quality and competitively priced aromatic petrochemicals. Such plants sell crude light oil to petroleum-refining companies for processing with petroleum-derived fractions into benzene, toluene, and a number of other chemical intermediates.

As with other coal-chemical materials, yields of products derived from crude light oil vary, but approximately 82 volume-percent of the crude light oil processed was recovered in 1974 as salable products; 60.2% as benzene, 11.5% as toluene, 2.7% as xylene, and 7.6% as other products. Approximately all of the benzene production was classed as specification grades. In past years, a large amount of motor-grade benzene was used to increase antiknock properties of gasoline, but present petroleum-refining techniques have all but eliminated this use for benzene.

The unit value of light oil derivatives sold in 1974 ranged from $0.763 per gallon for specification-grade benzene to $0.265 per gallon for all grades of solvent naphtha. The average value of all light oil products sold increased 181% to $0.705 per gallon.

WORLD REVIEW

World production of metallurgical coke in 1974 was estimated at 408.7 million short tons. This quantity was 2% higher than the 1973 output and the increase was attributed to large production gains in West Germany, Italy, the U.S.S.R., the United Kingdom, and Japan.

Europe, with 56% of the total, led in world production. European output was 4% greater than in 1973, mainly because of larger output in the U.S.S.R. Asia, with eight producing countries, ranked second in output while North America, with only three producing countries, ranked third.

The U.S.S.R., with nearly 23% of the world output, was the largest producer of coke. The U.S.S.R. production increased 3.7% over that of 1973; the estimated 93.1 million tons of coke and breeze produced in 1974 was a record output for the country. Metallurgical coke production, however, probably totaled about 88 million tons based on an estimated 5.1 million tons of breeze production.

The United States, with 15% of the world total, ranked second in production, and Japan, with 12%, ranked third. The United States had a 4.3% production decrease, but Japan's output was 3% above that of 1973.

Other leading coke-producing countries in order of output were West Germany, the People's Republic of China, Poland, the United Kingdom, and France. Although metallurgical-grade coke was produced in 30 other countries, the production of these five countries combined with that of the U.S.S.R., the United States, and Japan accounted for 79% of world production.

In addition to metallurgical-grade coke, which is produced at high-temperatures in conventional slot- and beehive-coke ovens, 19 million tons of other coke was produced at high, medium, and low temperatures in vertical and horizontal retorts and other types of carbonizing equipment. Commonly referred to as "gashouse" or "soft" coke, this material is not suitable for most metallurgical applications, but is used principally for domestic heating, chemical processing, and gas production. Production of "gashouse" coke has been declining in recent years, and the 1974 world output was only about one-fourth as large as that of a decade ago.

Nippon Steel Corp. (NSC) urged Japanese steelmakers to refrain from buying high-priced coking coal from the United States under spot contract conditions. NSC claimed that acceptance of the higher prices in the United States would stimulate other suppliers such as Canada, Australia, and the U.S.S.R. to raise prices to similar levels. The Japanese steel industry planned to import 16 million tons of U.S. coking coal, about 12 to 13 million tons of which were under long-term contracts that had fixed prices. It was also predicted that acceptance of high-priced coal under spot contracts would ultimately result in increases in the price of long-term contracts.

NSC developed an industrial process for using a substantial proportion of noncoking coal in a coke production venture. Advantages cited were that the consumption of coking coal could be reduced to 55% from 70%, thereby making it possible to decrease consumption of extra-hard coking coal from a previous minimum of 10% to 4% and that a low-operating-cost briquette-making plant would permit use, up to 20% of the total weight of coals used, of noncoking coal previously considered unusable in coke production.

The principal Canadian steel producers —Steel Company of Canada (Stelco), Dominion Foundries and Steel Ltd. (Dofasco), The Algoma Steel Corporation, Ltd. (Algoma), and others—continued to obtain most of their coking coal from the United States, largely from the Appalachian coalfields. Some shipments of western Canadian coking coal were made to eastern steel plants for testing. The new planned transshipping terminal at Thunder Bay, Ontario, could help move Canadian metallurgical coal eastward as well as thermal coal for powerplants.

TECHNOLOGY

The reduction of atmospheric pollution at coke plants continued to receive attention although no combinations of equipment proved to be totally effective and no major advances were forecast. The use of a hood to enclose the coke guide and coke car was described in British Patent 1,329,533 (1973) issued to The Koppers Co. Inc., and titled: "Improvements in or relating to preventing air pollution about coke ovens."

The method adopted at the Warren, Ohio, plant of Republic Steel Corp. to reduce air pollution during on-main charging of oven batteries equipped with a single collecting main was described.[4] A breeches pipe was substituted for one of the center hoppers of the charging car. This design reduced the emission 80%. Remaining problems comprised the difficulty in attaining a full charge of coal, lack of suction through the breeches pipe, an increase in leveling time, and possibly an increase in the pentane-insoluble content of the tar.

The British Carbonization Research Association (BCRA) in October 1974 issued the third edition of a 20-page special publication titled "Practical Suggestions for the Reduction of Smoke, Dust and Grit at Coke Ovens." Although most of the text relates to coke ovens, discussion is also given to the handling and stocking of coal, coke and other bulk materials, boilers and ancillaries, odors from coking plants, and the determination of the mass emission factor.

The smokeless-charging procedures developed for use at the Clairton Works of the United States Steel Corp. was described in an AIME publication.[5] The procedure comprises the sequential discharge of coal from hoppers of the charging car in conjunction with the use of ascension-pipe steam injectors of increased size operated at higher pressure to increase the capacity to aspirate the gases and vapors from the oven chamber. The coal leveler bar is provided with a specially designed muff.

USS Engineers and Consultants Inc. developed a system, described in British Patent 1,334,546, for the smokeless charging of coke ovens. A special charging main is provided in addition to normal double collecting mains and is located above one of the collecting mains. The special main is connected into the central offtake from the oven battery to the byproduct plant, downstream from the butterfly valves controlling the back pressure in the regular collecting mains. During oven charging, the drop sleeves of the charging car are connected by a duct system and flexible couplings to a side arm of the charging main. A vacuum equal to 25 millimeters of H_2O is maintained in the charging main in contrast to the positive pressure maintained in the regular collecting mains. An additional connection between the charging main and the collecting main below it is provided with a valve controlled by a gas analyzer so that the oxygen content in the charging main is kept below the lower explosive limit by the passage of coke oven gas from the regular collecting main.

[4] Mantz, G. H. Ironmaking Proc. AIME 1973, v. 32, pp. 271–275.

[5] Weber, G. T., and Lewis, R. E. Ironmaking Proc. AIME 1974, v. 33, pp. 276–286.

Construction activities and some initial break in runs of a formed coke pilot plant were continued at Sparrows Point, Md., by a consortium of four steel companies and one coal company. The plant is designed to use either coking-grade or weakly coking-grade coal. Other objectives of the project are to curtail gas and dust emissions at coke works, to stretch the supply of low-volatile coal by using a single high-volatile coal, and to use surplus gas from the process, after cleaning, in steel plants and for power generation.

A series of test runs using 20,000 tons of formed coke mixed with conventional byproduct coke were performed in a blast furnace a Inland Steel Co.'s Indiana Harbor Works, East Chicago, Ind. The furnace operation and iron quality were normal even when 50% of the coke requirement was supplied by formed coke made in the FMC Corp. Kemmerer, Wyo., plant using subbituminous Western coal.

British Patent 1,350,494 was issued in 1974 to Pullman Inc., for a process to produce formed coke for blast furnaces by briquetting dried, rushed, minus 10 mesh-noncaking or weakly caking coal with a residue from the thermal cracking of gas oil, and carbonizing the briquets. The heating rate in the critical temperature range 370° to 600° C is kept within defined limits to avoid the excess liquefaction of the binder that would occur with too low a rate and the fissuring of the briquets that would occur at too high a rate.[6]

Cupola tests using formed coke made by the IChPW process and incorporating desulfurizing additions such as 5% manganese ore or limestone were described.[7] Formed coke was used as a replacement for the charge coke only, and as a replacement for the charge coke and bed coke. The sulfur content of the cast iron was about 25% less than when using conventional oven coke.

The British Cast Iron Research Association found no improvements when the mean size of foundry coke was increased above 3.4 inches. The use of larger coke increased combustion efficiency, but it also increased the sensible heat loss.[8]

Five characteristics of good foundry coke that increased its efficient use in cupolas were discussed.[9] Foundry coke should be uniform in size, stability, strength, and density and have proper chemical composition. Ash, necessary to strength, should not exceed 8.0%.

Collective operational changes including longer coking time, improved coal pulverization, and increased bulk density resulted in improved coke stability, a measure of coke strength. The unit production of both 1,900-tons-per-day and 2,800-tons-per-day capacity blast furnaces increased as the coke stability increased. Production of hot metal increased almost 2% for each percent increase in stability. The effect of coal sizing was pronounced. For example, coal sized at 74% minus ⅛ inch produced a coke having 51.0 stability; coal pulverized to 85% minus 1/8 inch produced coke having 59.5 stability. Hot-metal production using 51.5-stability coke with a maximum attainable wind rate of 92,000 cubic feet per minute was 2,400 net tons per day; coke with 59.0 stability permitted a wind rate of 110,000 cubic feet per minute resulting in a hot-metal production of 2,800 net tons per day. The coke rate in pounds consumed per ton of hot metal produced decreased from 925 pounds to 885 pounds as the coke stability increased from 55.0 to 59.0.[10]

Simon-Carves Ltd., developed a process

in which coke is quenched by immersion in water. The coke is deposited on the surface of the water and is then moved along the surface or in suspension so that the lumps of coke sink while being saturated with water. The coke is moved along the bottom of the water bath from where it is transferred to an overhead belt conveyor where the adhering water evaporates. The volume of the water in the bath is sufficient to prevent the formation of quench vapors resulting in atmospheric pollution. The process is protected by British Patent 1,347,654 issued in 1974.

British Patent 1,349,186 issued to Firma Carl Still in 1974, describes a coke-oven-heating system in which air and lean gas are distributed to a heating flue through a vertical series of slots connected to a riser duct in the partition between the flue and the adjacent flue. The riser ducts are arranged in pairs (one pair for air and one pair for lean gas per flue). The system permits adjustment of the vertical heat distribution by changing the proportions of air or gas supplied to the riser ducts in each pair, which are connected to different regenerator chambers.

The addition of breeze to a coke-oven charge has a systematic influence on the tensile strength of coke when other carbonization factors are closely controlled. In general, the tensile strength progressively, though nonlinearly, decreases with increasing breeze addition. The extent of this effect depends on the particle size of the breeze. By using smaller particle sizes of breeze at low levels of addition, a coke of increased tensile strength can be produced. At higher levels of breeze addition, the strength is again decreased. A maximum coke tensile strength was obtained when the oven charge contained about 7.5 weight-percent of 63-micrometer breeze. Changes in tensile strength were accompanied by changes in porosity and apparent density. Changes in other textural parameters such as dimensions of the pores and pore walls were less clearly evident.[11]

The operating characteristics of high-capacity coke ovens, design concepts and economics were reviewed.[12] Subjects discussed included heating systems, refractories, heat consumption, carbon formation, and the future of high-capacity ovens.

Crude light oil and derivatives[7] do	$113,799	--	$113,799
Surplus gas do	$299,102	--	$299,102

W Withheld to avoid disclosing individual company confidential data.

[1] Not separately recorded.

[2] Plants associated with iron-blast furnaces.

[3] Data may not add to totals shown because of independent rounding.

[4] Included with "To other industrial plants" to avoid disclosing individual company confidential data.

[5] In terms of sulfate equivalent.

[6] Includes ammonium sulfate, ammonia liquor, and diammonium phosphate.

[7] Includes intermediate light oil.

Table 3.—Summary of oven-coke operations in the United States in 1974, by State

State	Plants in existence Dec. 31	Coal carbonized (thousand short tons)	Yield of coke from coal (percent)	Coke produced (thousand short tons)

e Estimate. p Preliminary. r Revised.

[1] In addition to the countries listed, Algeria, Australia, Malaysia, the People's Republic of China, Mexico, Norway, Romania, and the U.S.S.R. have produced gashouse coke in previous years and may have continued production during the time period covered by this table. However, no official statistics are available, and information is inadequate to make reliable estimates of production levels. Except where otherwise noted, coke breeze has been excluded from this table.

[2] Coke produced at high temperature in conventional carbonizing equipment (including slot and beehive coke ovens).

[3] Includes breeze.

[4] Includes relatively small amounts of gas coke.

[5] Includes 21,728 short tons of breeze coke and 18,613 short tons of imperial coke.

[6] May include some gas coke.

[7] Includes relatively small amounts of low-temperature coke.

[8] Data are total of so-called hard coke production from collieries and coke plants (including those at steelworks).

[9] Data are for years beginning March 21 of that stated.

[10] Includes coke produced at high temperatures in carbonizing equipment designed primarily for gas manufacture (horizontal and vertical coal-gas retorts). In addition to the countries listed, Canada and Finland produce gas coke. However, this figure is not reported separately and has been included with metallurgical coke.

[11] Less than ½ unit.

[12] Excludes small quantities of gashouse coke, which are included with metallurgical coke.

[13] Includes coke produced at low and medium temperatures, as well as that produced in unconventional equipment (chain-grate cokers). In addition to the countries listed, the U.S.S.R. may produce coke from brown coal, but output is not officially reported and no basis is available for reliably estimating output levels.

[14] Includes coke produced from lignite at high temperature.

Grand total[8]	--	--	585,866	--	--

[1] Includes products of tar distillation conducted by oven-coke operators under the same corporate names.

[2] Soft-water-softening point-less than 110° F; medium-110° to 160° F; hard-oven 160° F. Figures on hard pitch includes small amount of medium pitch, and also include hard pitch to avoid disclosing individual company confidential data.

[3] Creosote oil, cresols, cresylic acid, naphthalene, phenol, pyridine, refined tar, tar paint.

[4] Included with sulfate to avoid disclosing individual company confidential data.

[5] Includes gas used for heating ovens and gas wasted.

[6] Data may not add to totals shown because of independent rounding.

[7] Includes 121,363,000 gallons refined by coke-oven operators to make derived products shown.

[8] Included with "Specification grades" to avoid disclosing individual company confidential data.

Table 34.—Coal equivalent of the thermal materials, except coke, produced at oven-coke plants in the United States

Year	Materials produced				Estimated equivalent in heating value[1] (Billion Btu)					Coal equivalent (thousand short tons)
	Coke breeze (thousand short tons)	Surplus gas (billion cubic feet)	Tar (thousand gallons)	Light oil (thousand gallons)	Coke breeze	Surplus gas	Tar	Light oil	Total	
1970	4,665	585	760,926	244,107	93,300	321,750	114,139	31,734	560,923	21,409

[1] Included with Alabama to avoid disclosing individual company confidential data.

[2] Data may not add to totals shown because of independent rounding.

[3] Data not broken down into merchant and furnace plants to avoid disclosing individual company confidential data.

[4] Included with Pennsylvania to avoid disclosing individual company confidential data.

Columbium and Tantalum

By Henry E. Stipp [1]

Consumption of columbium in 1974 increased 14% over that of 1973 to a new record high totaling about 4.6 million pounds of contained columbium and tantalum. Consumption was in the form of ferrocolumbium, ferrotantalum-columbium, and other columbium and tantalum materials. Columbium and tantalum are used in steel to stabilize carbon and nitrogen, improve the yield strength, decrease weight, and increase the weldability. Columbium steels are being used increasingly for applications in pipelines, automobiles, railroads, heavy equipment, construction, and shipbuilding.

Demand for tantalum in the first three quarters of 1974 increased substantially, resulting in record high prices for tantalum concentrates. Prices for columbium mineral concentrates also increased.

Imports of columbium and tantalum mineral concentrates (gross weight) increased 11% and 73%, respectively, over those of 1973. Ferrocolumbium imports, mainly from Brazil, increased 55% to 3,276,000 pounds, a record high compared with similar imports in 1973. Research on the use of columbium alloys as super-conductors of electricity at cryogenic temperatures received increasing attention.

Legislation and Government Programs.—The columbium and tantalum disposal program of the General Services Administration (GSA) continued with sales of 2,162,226 pounds of columbium concentrate (Cb content) and 394,122 pounds of tantalum minerals (Ta content). Several bills for disposing of additional quantities of stockpiled columbium and tantalum materials were submitted for congressional consideration.

GSA changed the conditions for sale of stockpile tantalum after a meeting with the U.S. Tantalum Producers Association on March 19. The new conditions of sale included a rule that no more than 25,000 pounds of contained tantalum would be awarded to any one firm or its affiliates. In addition, the buyer must guarantee that any tantalum bought from GSA will be consumed in the United States within 90 days of sale. Any resale of GSA material would be made under the new provisions.

Table 1.—Salient columbium statistics
(Thousand pounds)

	1970	1971	1972	1973	1974

[1] Includes 149,590 pounds of nonstockpile-grade material.

DOMESTIC PRODUCTION

There was no domestic production of columbium and tantalum minerals reported during the year.

Columbium metal powder produced in 1974 decreased 19% compared with that of 1973. However, specific data is withheld to avoid disclosing confidential company information. Columbium metal ingot production, also withheld to avoid disclosing confidential company data, decreased 4% compared with that in 1973. Tantalum metal powder production (including capacitor-grade powder) increased 14% to 925 tons compared with 810 tons in 1973. Tantalum metal ingot production totaled 356 tons, the same as that of 1973.

Ferrocolumbium was produced in 1974 by three companies.

Table 4.—Major domestic columbium and tantalum processing and producing companies in 1974

CONSUMPTION AND USES

Columbium consumed in the form of high-purity metal decreased 13% to 220,696 pounds compared with 253,882 pounds in 1973. The primary end use for high-purity columbium metal, in powder and ingot form, was in high-temperature superalloys required mainly by the aerospace industry.

Consumption of tantalum metal, including capacitor-grade powder, increased 6% to 1,159,201 pounds compared with 1,095,694 pounds in 1973. The principal end use for tantalum metal, in powder and ingot form, was in the manufacture of capacitors and other electronic equipment, and corrosion-resistant chemical equipment.

Ferrocolumbium, ferrotantalum-columbium, and other columbium and tantalum materials consumed in steelmaking increased 4% to a total 3,388,601 pounds of contained columbium and tantalum compared with 3,253,822 pounds in 1973.

Columbium and tantalum in the form of ferroalloys, added to steels to control grain size and improve strength and weldability, accounted for 73% of the total consumption of ferrocolumbium, ferrotantalum-columbium, and other columbium and tantalum materials. Consumption of ferrocolumbium, ferrotantalum-columbium, and other columbium and tantalum materials increased in all end-use categories except stainless and heat-resisting steel. Consumption in that category decreased 21% from that of 1973.

Domestic consumption of columbium and tantalum in ferroalloy forms, by major end-use categories, was as follows: High-strength, low-alloy steels, 27%; superalloys, 24%; carbon steel, 22%; stainless and heat-resisting steel, 12%; and full alloy, 11%. Consumption of ferrotantalum-columbium continued to be negligible; it accounted for less than 1% of the total consumption of columbium and tantalum in the form of ferrocolumbium, ferrotantalum-columbium, and other columbium and tantalum materials. The major end use for ferrotantalum-columbium was in stainless and heat-resisting steel.

Demand for columbium in alloy plate steel for use in oil and gas pipelines was expected to increase significantly during the next few years. Columbium in the form of ferrocolumbium is added to pipeline and heavy-plate steels to increase low-temperature strength and toughness.

High-strength, low-alloy steel used in automobiles currently totals about 70 pounds per vehicle. It is estimated that by 1980 approximately 200 pounds per vehicle would be used in order to make cars lighter but stronger.[2]

A columbium-germanium alloy reportedly has potential for use in electrical power transmission cables, electric magnets for fusion reactors, rotating electrical machinery, train and ship propulsion devices, generators, and low-power electrical devices.

Alloys (excluding alloy steels and superalloys)	82,766
Miscellaneous and unspecified	56,824
Total	4,625,826

W Withheld to avoid disclosing individual company confidential data; included in "Miscellaneous and unspecified."

STOCKS

Columbium and tantalum materials in processor and dealer inventories at yearend were as follows in pounds:

Material	Dec. 31, 1973	Dec. 31, 1974
COLUMBIUM		
Primary metal	108,697	89,203
Ingot	51,290	36,548
Scrap	80,025	112,817
Oxide	495,451	536,538
Other compounds	13,946	12,369
TANTALUM		
Primary metal	[r]220,525	213,855
Capacitor-grade powder	135,098	110,395
Ingot	65,088	82,620
Scrap	258,568	329,697
Oxide	37,101	69,580
Potassium tantalum fluoride	130,763	138,673
Other compounds	31,051	57,621

[r] Revised.

Stocks of columbium and tantalum raw materials, reported by processors and dealers at yearend 1974, in short tons (gross weight), 1973 figures in parentheses, were as follows: Columbite, 1,511 (1,310); tantalite, 1,079 (745); pyrochlore, 208 (229); and tin slag, 33,695 (34,691).

Ferrocolumbium and ferrotantalum-columbium stocks held by consumers as of December 31, 1974, were as follows (1973 yearend stocks in parentheses): Ferrocolumbium, 1,719,425 pounds of contained columbium (1,456,283); ferrotantalum-columbium, 10,837 pounds of contained columbium and tantalum (22,867); and other columbium and tantalum materials, 46,947 pounds of contained columbium and tantalum (47,182). Producer stocks of ferrocolumbium at yearend 1974 were 946,400 pounds of contained columbium (774,800).

PRICES

Prices for columbite and pyrochlore increased in 1974. Contract rates for Canadian pyrochlore, f.o.b. mine and mill, increased from $1.44 per pound of Cb_2O_5 to $1.80 per pound at yearend. Brazilian pyrochlore similarly increased from $1.42 per pound of CB_2O_5 content to $1.56. Columbite ore, c.i.f. U.S. ports, increased from $1.45 per pound of contained pentoxides for material having a CB_2O_5-to-Ta_2O_5 ratio of 10 to 1, to $1.80 per pound at yearend.

Tanco tantalite at the beginning of the year was quoted at $10 per pound of contained Ta_2O_5; by yearend, the price was $15. Spot prices for other tantalite ores or concentrates at the beginning of the year were quoted at $8.50 to $10 per pound of Ta_2O_5, 60% basis, c.i.f. U.S. ports; at yearend prices were $13 to $15.

At the beginning of the year, Thailand tin slag from the Union Carbide-Billiton tin smelter, 12%-Ta_2O_5 content, was quoted at $4.50 per pound of contained Ta_2O_5; at yearend, the price was $5.

Prices at the beginning of the year for various grades of ferrocolumbium per pound of contained columbium (ton lots, f.o.b. shipping point) were low-alloy grades, $3.10, and high-purity grades, $5.00 to $5.26. At yearend, prices had increased to $4.12 for low-alloy grades (15:1 ratio) and $8.61 to $8.65 for high-purity grades.

The price of columbium metal increased during the year. Columbium powder, reactor grade, was quoted at $12 to $23 per pound from January 1 to June 1, and $30 to $45 per pound through yearend. Reactor-grade columbium ingot was quoted at $17.50 to $28 from January 1 to June 1, and $18 to $25 through yearend.

Tantalum metal prices from January 1 to October 16 were quoted as follows: Powder, $30 to $37; rod, $30 to $40; and sheet, $36 to $60. Prices for tantalum metal from October 17 through yearend were as follows: Powder, $35.40 to $44.50; rod, $45 to $54; and sheet, $50 to $57.

Table 7.—Average grade of concentrate received by U.S. consumers and dealers in 1974, by country of origin

[1] Material reported from Brazil as columbite represents primarily pyrochlore.

FOREIGN TRADE

U.S. exports of unwrought columbium and columbium alloys, and waste and scrap were shipped mainly to West Germany (43%), the United Kingdom (43%), and Japan (9%). Wrought columbium and columbium alloys went chiefly to West Germany (39%), Canada (21%), and Japan (15%).

U.S. exports of tantalum ores and concentrates were shipped chiefly to West Germany (54%) and Japan (45%). Wrought tantalum and tantalum alloys n.e.s., shipped from the United States in 1974 went mainly to Japan (33%), West Germany (19%), and the United Kingdom (19%). Unwrought tantalum metals and alloys, and waste and scrap shipped from the United States went mainly to West Germany (88%), Japan (7%), and Mexico (2%). U.S. exports of tantalum and tantalum-alloy powder went chiefly to Japan (32%), West Germany (21%), and the United Kingdom (19%).

Imports for consumption of unwrought columbium metal, and waste and scrap, from West Germany (64%) and the Netherlands (36%), totaled 481 pounds valued at $6,658. There were no imports of unwrought columbium alloys and wrought columbium metal in 1974.

Unwrought tantalum metal, and waste and scrap imported for consumption totaled 183,788 pounds valued at about $1.6 million; these imports were mainly from West Germany (43%), the United Kingdom (34%), and Mexico (17%). Unwrought tantalum alloys, all from West Germany, totaled 18 pounds valued at $979. Wrought tantalum, imported mainly from the United Kingdom (65%), totaled 376 pounds valued at $16,069.

Imports for consumption of columbium mineral concentrates and tantalum mineral concentrates in 1974 increased 11% and 73%, respectively, over 1973 imports.

Tin slag receipts in 1974 came chiefly from Thailand.

Table 8.—U.S. exports of columbium and tantalum, by class

(Thousand pounds, gross weight, and thousand dollars)

Class	1973		1974	
	Quantity	Value	Quantity	Value

WORLD REVIEW

Australia.—Tantalite-columbite mineralization in the Pilbara area of Northwestern Australia is confined to pegmatites associated with granitic rocks. Large pegmatite structures about 2,000 feet long, occurring as dikes and segregations within the granites and Archaean fringe rocks, carry tantalum, columbium, tin, lithium, beryllium, and rare-earth minerals. Pegmatites in the Wodgina, Tabba Tabba, Strelley, and Pilgangoora areas are intruded into jaspilites, quartzites, and slates and interbedded with massive and sheared amphibolites; they contain economic deposits of tantalite, columbite, and beryl. Total production of tantalite and columbite from the region was as follows, in tons (gross weight): Pilgangoora, 34.5; Strelley, 30.5; Tabba Tabba, 19.3; and Wodgina, 242.8.[3]

Brazil.—Brasimet Comercio e Industria S.A., a subsidiary of South American Consolidated Enterprises of the Hochschild Group, was developing its Catalão pyrochlore deposit located in the State of Goiás. A 1,000-ton-per-day mill to beneficiate the pyrochlore was being constructed near the deposit.[4]

---

[3] Liddy, J. C. The Mineral Potential of North-Western Australia. Australian Min., v. 66, No. 6, June 1974, pp. 31–38.

Companhia Brasileira de Metalúrgia e Mineração (CBMM) reportedly began expanding its pyrochlore production capacity from its 1974 rate of 28 million pounds of Cb_2O_5 content per year to about 40 million pounds per year by yearend 1976. CBMM produced pyrochlore concentrate from a deposit near Araxá, which contains ore averaging 3.5% Cb_2O_5 content. The company processed about 50% of its production into ferrocolumbium at a plant in Araxá. CBMM is owned by Brazilian interests (50.5%), Molybdenum Corp. of America (33%), and Pato Consolidated Gold Dredging, Ltd. (16.5%).

Two reports were published that described the geology, mineralogy, reserves, mining, and beneficiation of pyrochlore and columbite-tantalite deposits in Brazil.[5]

Canada.—Indicated and proven ore reserves at the St. Lawrence Columbium and Metals Corp. deposit, Oka, Quebec, were increased from 7.4 million tons to a total of 25.4 million tons grading 0.43% Cb_2O_5. This resulted from the discovery of two additional pyrochlore ore zones in June 1973. St. Lawrence planned to increase mill output to 3,000 tons per day from the present 2,200 tons per day. The firm milled 328,344 tons of ore during the 6 months ended March 1974.[6]

The St. Honoré columbium deposit near Chicoutimi, Quebec, was scheduled for development by Niobec Inc. at an estimated capital cost of $12.7 million. Production of 5.5 million pounds of Cb_2O_5 was expected to begin in early 1976. Reserves were reported as 40 million tons of 0.76% Cb_2O_5 to a depth of 850 feet. Niobec Inc. is owned by Quebec Mining Exploration Co. (SOQUEM), a Quebec provincial corporation (50%), Teck Corp. Ltd. (25%), and Copperfields Mining Corp. Ltd. (25%).[7]

Canada's shipments of columbium concentrates in 1974 were valued at $6.5 million (preliminary) compared with $3.2 million in 1973. The bulk of Canada's columbium concentrate, containing from 51% to 54% Cb_2O_5, is exported to Europe for use in the steel industry. Some columbium concentrate is processed to ferrocolumbium by St. Lawrence Columbium and Metals Corp., Oka, Quebec; Masterloy Products Ltd., Gloucester, Ontario; and Fundy Chemical International Ltd., Surrey, British Columbia.[8]

Chemalloy Minerals Ltd. sold a 24.9% interest in its subsidiary, Tantalum Mining Corp. of Canada, Ltd., (TANCO) to Kawecki Berylco Industries, Inc., of the United States. Chemalloy retained 50.1% interest in Tantalum Mining. The Manitoba Development Corp., a provincial agency, owns 25% of Tantalum Mining.[9]

The Tanco mine and plant at Bernic Lake was shut down in June 1973 reportedly because of the low market price for tantalum concentrate, which was below Tanco's minimum price of $10 per pound of Ta_2O_5 content. Operations resumed in January 1974. Reserves of tantalite ore at Tanco's mine were reported at yearend 1974 as 1,261,469 tons averaging 0.221% Ta_2O_5. Shipments of tantalum concentrate from Canada in 1974 totaled 430,000 pounds Ta_2O_5 (preliminary) in concentrates valued at $3,646,000 compared with shipments of 170,582 pounds Ta_2O_5 valued at $1,164,749 in 1973.[10]

Mozambique.—Revolutionary disturbances were not expected to interrupt mining or shipping of tantalite ore and concentrate for long. An independent Mozambique reportedly will have to sell tantalum concentrate to obtain foreign currency.[11]

Thailand.—Shipments of tin slags from Thailand Smelting and Refining Co. Ltd.'s smelter were returning to normal in March after an interruption caused by the lack of steel drums. Thailand tin slags, which contain about 12% Ta_2O_5, were sold out under long-term contracts until 1977.[12]

concentrates, recovered as a byproduct of tin mining, has been decreasing recently as a result of depletion of onshore tin mines, and the increasing cost of fuel. According to the Thailand Department of Mineral Resources, the number of tin mines in Thailand decreased by one-third during 1973, to 441 mines. A further decrease occurred in 1974. By contrast, production from large offshore dredging operations increased. During 1973, the number of offshore dredges increased from 6 to 10.[13]

United Kingdom.—Exports of ferrocolumbium from the United Kingdom were halted from February 18 as part of the Government export restrictions on iron and steel products.[14] The exports restrictions were imposed to safeguard United Kingdom steel and ferroalloy supplies, which have been reduced as a result of a coal strike. Reportedly, the ban would be lifted when steel and ferroalloy inventories have been increased to pre-strike levels.

TECHNOLOGY

Research in the field of superconductivity involving columbium alloys continued with new discoveries that could result in wider application for columbium materials. A chemical vapor deposition process was used to form a columbium-germanium alloy on a metallic or insulating substrate. Samples of columbium-germanium alloy previously were prepared for laboratory use by a sputtering process, which was not easily adaptable for commercial purposes. Columbium-germanium superconducting material can be prepared in commercial quantities using the chemical vapor process, thus facilitating practical application of the alloy.[15]

Oxidation studies on columbium-based alloys FS-85 and SU-31 and a disilicide coating established that neither alloy was entirely oxidation resistant and neither alloy could be used for gas turbine applications above 2,000° F without a protective coating. The disilicide coating protected both alloys against static oxidation for at least 200 hours at 1,600° F through 2,500° F.[16]

A new steel containing 0.06% columbium, 1.60% manganese, and 0.25% molybdenum was reported to have high strength, toughness, and weldability. The steel was designed for commercial applications that require yield strengths of 70,000 pounds to 100,000 pounds per square inch. Developed for pipelines subject to subzero arctic conditions, the columbium-manganese-molybdenum steel was able to maintain toughness well below 0° F.[17]

A stainless steel containing columbium and titanium that withstands temperatures of up to 300° C without developing corrosion cracks was developed by the Japanese Science and Technology Metal Material Research Center. The chromium ferrite-type steel contains no nickel; however, it has better heat conductivity than some stainless steels and can be used for pressure vessels, heat exchangers, and other high-pressure products.[18]

A high-purity tantalum evaporation filament was developed for resistance and RF/Bias evaporation of thin films by Materials Research Corp. The filaments, fabricated from electron-beam-refined tantalum, had low alkali impurity, consistent electrical properties, and maximum filament life.[19]

A study of the effect of carbon on the electrical resistivity of columbium and tantalum was reported. The electrical resistivity of columbium and tantalum, measured between 1,500° C and 2,100° C, increased linearly with the concentration of carbon within the alpha solid solution range.[20]

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Excludes columbium and tantalum-bearing tin concentrates and slag.

[2] In addition to the countries listed, Burundi, Spain, South West Africa, and the U.S.S.R. also produce or are believed to produce columbium and tantalum mineral concentrates, but available information is inadequate to make reliable estimates of output levels.

[3] Data on gross weight generally has been presented as reported in sources, divided into concentrates of columbite, tantalite, pyrochlore and microlite where information is available to do so, and reported in groups such as columbite-tantalite where it is not.

[4] Unless otherwise specified, content is estimated on the basis of the content reported for United States imports from the country in question. Estimates specifically marked as estimates are based on estimated gross weights.

[5] Content calculated on the basis of data in source publication recording gross weight.

[6] Less than ½ unit.

[7] Content calculated in terms of metal from data reported in source publication in terms of contained pentoxide.

Tantalum carbide fiber grown by an alternating-current discharge method was studied. Maximum growth rates of up to 40 millimeters per minute were obtained with a minimum diameter of 3.5 microns. The tensile strength was 2.7 kilograms per square millimeter.[21]

The effect of oxygen on the corrosion of columbium and tantalum metal (99.9% pure) by liquid lithium at 600° C was studied. Lithium penetrated the metals when the oxygen concentration of the refractory metals exceeded a threshold level. Penetration resulted from formation of a ternary oxide, and proceeded by a wedging mechanism either intergranularly or along specific crystallographic planes, depending upon the oxygen concentration. The oxygen in the lithium did not increase the dissolution of the metals.[22]

An increasing interest in the recovery of columbium and tantalum from low-grade materials was shown by some of the patents issued in 1974.[23]

Copper

By Harold J. Schroeder [1] and George J. Coakley [1]

World mine production attained 8.10 million tons, a record high for the seventh consecutive year, but the 3% rate of growth was the smallest since 1971. Among the major producers, Chile, Poland, and Australia recorded significant increases in production while the United States and Zambia had reduced outputs. During the first half of the year a high level of demand for copper increased prices to record highs and stimulated production. However, during the second half of the year a worldwide recession reduced demand and caused a precipitous drop in prices, and a rapid buildup in stocks of copper. A series of production cutbacks near yearend was an attempt to seek a balance between supply and demand.

[r] Revised.

In the United States consumption of refined copper and mine, smelter, and refinery outputs were all substantially smaller. Strikes at most producing units during portions of July and August and reduced demand for copper in the latter half of the year were factors that adversely affected the level of activity. Imported copper was a larger component of supply as imports of unmanufactured copper increased significantly while exports declined. An additional component of supply in 1974 resulted from the sale or commitment during the months of February through May of all of the approximately 252,000 tons of refined copper remaining in the national stockpile. Industrial stocks of refined copper increased since the supply of copper from production, net imports, and Government stockpile releases exceeded consumption. The domestic price for cathode copper was restricted to 68 cents per pound until removal of price controls at the end of April after which the price advanced in two steps to a record high of 85 cents per pound on June 1, then, reflecting changing market conditions, was reduced in four steps to a dual 68- and 72-cent-per-pound quotation at yearend.

Legislation and Government Programs.—Copper held in the national stockpile on January 1, 1974, included 60,112 tons of oxygen-free, high-conductivity (OFHC) copper, 7,067 tons of copper in beryllium-copper master alloys, and 191,480 tons of copper in "other" classifications, a total of 258,659 tons Public Law 93–214 signed into law on December 28, 1973, authorized the disposal of all of the stockpile copper except the relatively small quantity in the form of beryllium-copper master alloys. In accordance with this authorization the General Services Administration (GSA) transferred 85,000 tons to the Bureau of the Mint and announced sealed bid sale awards on February 20, April 2, and May 24 for approximately 45,300 tons, 60,000 tons, and 39,000 tons, respectively. The remaining quantity, approximately 22,400 tons, was made available for defense set-aside sales and all but 489 tons was disposed of by yearend.

The Office of Minerals Exploration continued to offer up to 50% government participation in the authorized cost of exploration for copper deposits. There were no contracts executed in 1974 that involved copper.

Defense set-asides for controlled copper materials were in effect for certain brass mill, wire mill, and foundry products. The controlled items and their percent set-asides were as follows: Unalloyed brass mill products—sheet (2), rod (9), and tube (2); alloyed brass mill products—sheet (4) and rod (10); copper wire mill products (2); and copper foundry products (3). In February a set-aside for refined copper produced from domestically mined ore was established at a level of 5% of shipments, using the fourth quarter of 1973 as the base period. A proposal to broaden the base for copper set-asides to include all copper materials except scrap, of both domestic and foreign origin, was published in the Federal Register in September. However, no further action was taken on the proposal.

The duty on unmanufactured copper remained at 0.8 cent per pound. However, duties were suspended by Public Law 93–77, effective from July 1, 1973 to June 30, 1974, and by Public Law 93–497, effective from July 1, 1974 to June 30, 1975.

DOMESTIC PRODUCTION

PRIMARY COPPER

Mine Production.—Domestic mine production of recoverable copper was 1.60 million tons, a 7% decline and the smallest quantity since 1971. Principal copper producing States were Arizona, with 54% of the total, Utah (14%), New Mexico, (12%), Montana (8%), Nevada (5%), and Michigan (4%). These States accounted for 97% of total production. Strikes at most producing units during portions of July and August adversely affected output. Also in response to reduced demand for copper several producers made announcements in November and December of decisions to curtail operations.

Open pit mines accounted for 81% of mine output and underground mines for 19%. The production of copper from dump and in-place leaching, mainly recovered by precipitation with iron, was 146,107 tons or 9% of mine output. Total copper recovered by leaching methods was 222,633 tons, of which 192,640 tons was precipitated with iron and 29,993 tons was electrowon.

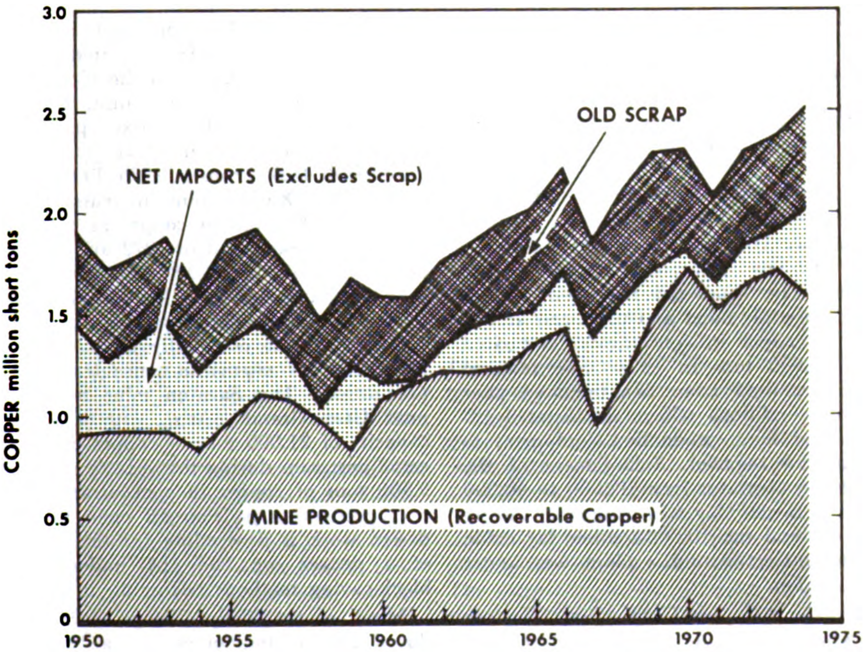

Figure 1.—Sources of copper supply for United States copper consumption.

Duval Corp., a subsidiary of Pennzoil Company, operated the Duval Sierrita open pit near Tuscon, Ariz., milling a record 30.9 million tons of ore averaging 0.29% copper and 0.026% molybdenum. Reserves at yearend were estimated at 554 million tons grading 0.32% copper and 0.033% molybdenum. Duval also operated the Esperanza and Mineral Park copper molybdenum open pit mines in Arizona and the Copper Canyon open pit copper mine in Nevada. These three operations milled 14.6 million tons of ore and also produced leach-precipitation copper from waste dumps. Total output from all operations was 121,080 tons of copper in concentrates and 11,500 tons of copper in precipitates.

The Anaconda Company produced 17,450 tons of copper from underground operations at Butte, Mont., compared with

21,670 tons in 1973. In September, the company announced its decision to phase out these underground operations because of the escalating cost of production and the declining price of copper. An extensive exploration program and feasibility study for large-volume, mechanized underground mining to ultimately produce copper from indicated vast quantities of deep, low-grade ore reserves has been started. In the interim an expansion of open pit operations is expected to largely offset the loss of underground production. The Berkeley pit produced 98,890 tons of copper compared with 104,470 tons in 1973 and the Continental-East pit, in its first full year of operation, produced 15,680 tons of copper. Production at the Yerington mine at Weed Heights, Nev., was 37,970 tons of copper. Work was near completion on the Victoria open pit copper mine and 1,000-ton-per-day concentrator near Ely, Nev. A major underground copper mine with an associated 10,000-ton-per-day concentrator, the Carr Fork project in the Bingham District of Utah, was under development with completion scheduled for 1979.

Anamax Mining Company, a joint venture of The Anaconda Company and AMAX, Inc., operated the Twin Buttes, Ariz., open pit mine and produced 40,140 tons of copper in concentrates compared with 73,650 tons in 1973. The reduced output resulted from unanticipated poor ground conditions which necessitated diversion of mine production equipment to overburden removal. Enlargement of the sulfide concentrator from 32,000 to 40,000 tons of ore per day was completed during the year and the 10,000-ton-per-day oxide ore leach-electrowinning plant was under construction.

Kennecott Copper Corp. operated mines in Arizona, Nevada, New Mexico, and Utah; these mines produced a combined total of 402,200 tons of copper, compared with 471,700 tons in 1973. The Utah Copper Div. accounted for 229,300 tons of the total followed by the Ray Mines Div. (Arizona) with 74,700 tons, the Chino Mines Div. (New Mexico) with 60,600 tons, and the Nevada Mines Div. with 37,600 tons. Severe weather conditions early in the year hampered production in Utah, output at the Nevada mine was reduced by temporarily lower ore grade, and all operations were disrupted by midyear strikes of 1 to 3 weeks' duration. New copper flotation equipment with higher copper recovery capability was installed at the Ray Mines Div. Kennecott also increased its capacity to treat copper silicate ore at Ray from 10,000 to 14,000 tons per day with an expansion of the copper ore leaching plant. Evaluation of a potential copper ore deposit beneath the perimeter of the Utah Copper Division's open pit continued. Plans include sinking a shaft, underground core drilling, and test mining to determine ground conditions and to obtain bulk samples for metallurgical testing. An environmental impact report was filed with the State of Wisconsin describing plans for developing an open pit copper mine near Ladysmith.

The American Smelting and Refining Company (ASARCO, Incorporated) operated three copper mines in the vicinity of Tucson, Ariz. The Mission unit, affected by a month-long labor strike, produced 40,300 tons of copper in concentrate compared with 46,600 tons in 1973. Production at the San Xavier mine increased from 2,700 to 5,900 tons of copper as the new leach plant completed in 1973 approached design capacity of 12,000 tons of copper in precipitates per year by yearend. The Silver Bell unit was unaffected by the strike and output was essentially unchanged at 23,500 tons of copper in concentrates and precipitates. The Sacaton mine and mill near Casa Grande, Ariz., with a design capacity of 21,000 tons of copper per year came onstream during the year to produce 9,500 tons of copper in concentrate. Current production is from an open pit but design work is proceeding for the mining of a deeper ore body by underground block-caving methods beginning in 1980.

Mines of the Phelps Dodge Corp. produced 281,338 tons of copper, a 12% decline from the 1973 record high. The decrease reflected strikes at the Arizona mines from July 15 to August 19, closure of open pit operations at Bisbee, and reduced work schedules. The Arizona mines at Morenci, Ajo, and Bisbee produced 112,790 tons, 43,501 tons, and 26,890 tons, respectively. Output at Tyrone, N. Mex., was 97,030 tons, and 1,127 tons was produced from miscellaneous sources. At Bisbee the Lavender pit was closed December 14 because of exhaustion of ore reserves, and continued operation of the underground mine was threatened by rising costs and declining copper prices. The $200 million Metcalf mine project near Morenci with a capacity to produce 60,000 tons per year of copper in concentrate was essentially completed by yearend. Underground development work continued at Safford, Ariz., to determine the feasibility of mining a deep ore body containing an estimated 400 million tons of ore with an average grade of 0.72% copper.

Cities Service Co., through its North American Chemicals and Metals Group, operated mines in Arizona and Tennessee that produced 30,600 tons of copper in concentrate compared with 39,600 tons in 1973. The Pinto Valley open pit mine and mill facilities near Miami, Ariz., were completed ahead of schedule and initial production began in June. Design capacity of 40,000 tons of ore per day or 60,000 tons of copper annually was expected to be achieved by early 1975. Development of the underground Miami-East mine continued and production from this relatively high-grade ore body is expected to begin in early 1976 and to reach a 2,000-ton-per-day level in 1978. In-place reserves of the Copper Cities and Diamond H mines near Miami will be exhausted early in 1975 but leaching operations at declining rates will continue for several years. A solvent extraction-electrowinning plant to replace the leach-precipitation plant was under construction with completion scheduled for mid-1976.

The White Pine, Mich., operations of White Pine Copper Co. milled 8.3 million tons of copper ore averaging 1.08% copper with an 85.7% recovery of copper in concentrate. As part of the cost reduction programs initiated in 1973, six new mobile rock-breaking devices known as feeder breakers were installed during 1974. These units enable efficient moveup of conveyor belts close to the mining faces which significantly reduces vehicle haulage and belt maintenance. Seven additional units are planned for 1975.

Magma Copper Co. operated the San Manuel and Superior underground copper mines in Arizona with a combined output of 149,600 tons of copper in concentrate compared with 158,300 tons in 1973. A 5-week strike during midyear and a cutback in operations near yearend curtailed production. Production at Superior continued to rise towards the 3,300-ton-of-ore-per-day rated capacity and during the fourth quarter averaged 3,000 tons. At the San Manuel mine two new hoisting shafts were completed to service production from deeper levels and to enable development of the adjacent down-faulted Kalamazoo section of the ore body.

The Inspiration Consolidated Copper Co. operated open pit copper mines in the vicinity of Inspiration, Ariz.; 18.5 million tons of waste and 8.5 million tons of ore were mined for a combined record high 27 million tons of material handled. Approximately 6.2 million tons of the ore was treated in the concentrator with about 47% of the concentrator feed first processed in leaching tanks to recover acid soluble copper. The combined production from in-plant processed ore in the form of concentrates, precipitates, and electrowon cathodes was 40,757 tons of copper. Heap-leaching of ore too low in copper content for in-plant treatment yielded an additional 8,943 tons of copper. Copper production from the Ox Hide mine was 4,840 tons from processing 3.4 million tons of ore. At the Christmas open pit mine, southeast of Miami, Ariz., output was 6,698 tons from processing 1.7 million tons of ore. The ratio of waste removed per ton of ore mined declined from 5.77 to 5.04. Total mine production from all operating mines was 61,238 tons of copper.

The Cyprus Pima Mining Co. operated the open pit Pima mine near Tucson, Ariz., milling 20 million tons of ore at a daily average rate of about 55,000 tons per day. Results of an extensive drilling program were being evaluated to determine if expansion of the present pit can be profitable. The expansion would require relocation of many existing support facilities and the old mill. Cyprus Bagdad Copper Co. at its Bagdad, Ariz., property produced about 12,000 tons of copper in concentrate from milling 2.17 million tons of sulfide ore averaging 0.74% copper. An additional 5,840 tons of copper was produced from oxide ore by a leach-electrowinning process. A major mine-mill expansion program designed to handle 40,000 tons of ore per day is planned to be completed by late 1977. Ore reserves at yearend were 300 million tons of proven ore averaging 0.49% copper, with additional tonnages indicated. The Cyprus Bruce Copper and Zinc Co. operated its underground copper-zinc mine near Bagdad, Ariz., and mined about 93,000 tons of ore grading 3.86% copper and 13.6% zinc. The Cyprus Johnson Copper Co. continued development of an oxide-copper ore deposit near Johnson, Ariz., with production scheduled for mid-1975 at a rate of 10,000 tons of ore per day. A leach-electrowinning process will recover about 5,000 tons of copper annually as cathodes. Reserves consist of 14.7 million tons of oxide ore with 0.80% total copper content which assures a life for the operation of about 10 years. An additional 10 million tons of mixed oxide and sulfide ore underlie the oxide deposit.

Ranchers Exploration & Development Corp. mined 4.5 million tons of ore and 4.7 million tons of waste to produce a record 7,487 tons of copper cathodes by a leaching-solvent extraction-electrowinning process at its Bluebird mine near Miami, Ariz. An expansion to increase capacity by 50% was planned for completion in 1976. Ore reserves were estimated to exceed 75 million tons. The *in situ* leaching operation at the Old Reliable deposit near San Manuel, Ariz., in the first full year of rated capacity operation, produced 2,688 tons of copper as a precipitate. At the Big Mike mine near Winnemucca, Nev., leaching operations yielded 580 tons of copper in precipitates compared with 971 tons in 1973.

Hecla Mining Co. in a joint venture with El Paso Natural Gas Co. continued mine development and plant construction at the Lakeshore copper mine south of Casa Grande, Ariz. The $185 million project is scheduled for production in the third quarter of 1975 with output to gradually build up to 65,000 tons of copper per year. Sulfide ore will be milled in a 9,000-ton-per-day concentrator with the concentrate treated by roasting, leaching, and electrowinning to produce 30,000 tons per year of cathode copper. The roasting operation will produce 200 tons per day of sulfuric acid for use in a 6,000-ton-per-day vat leaching plant to process oxide ore. The leach plant output will be 35,000 tons of copper in the form of precipitate copper.

UV Industries, Inc., operated its Continental mine near Bayard, N. Mex. Output was 24,167 tons of copper in concentrate from milling a record 1,701,000 tons of ore averaging 1.98% copper. Reserves at yearend were 16 million tons averaging 1.06% copper suitable for open pit mining and 7.5 million tons averaging 2.29 million tons suitable for underground mining.

Smelter Production.—Output of copper at primary smelters in the United States was 1.65 million tons, a 9% decrease from the record high of 1973 and the smallest quantity since 1971. The reduced production reflects disruptions by strikes at most smelters during portions of July and August.

ASARCO dedicated a 200-ton-per-day liquid sulfur dioxide plant at its Tacoma, Wash., smelter. This new plant plus the existing acid plant gives a capability to collect approximately 50% of the sulfur content of the copper concentrates processed by the smelters. At the Hayden, Ariz., smelter a 1,000-foot stack with connecting flues was completed in June. This stack in conjunction with an existing acid plant is expected to reduce sulfur concentrations to a level that will be in compliance with Federal ambient air quality standards. Also a highly sophisticated air monitoring and meteorological measurement system is in process of installation. At the El Paso, Tex., smelter a second acid plant is planned to collect sulfur emissions from both the copper smelter and the sinter machine of the lead smelter.

Anaconda completed installation of a baghouse and auxiliary equipment in a continuation of efforts to reduce emissions of particulates and sulfur dioxide gas to the atmosphere. An environmental monitoring system utilizing telemetry and computer components became operational during the year. A new fluid-bed roaster and electric furnace complex is under construction and when completed by the end of 1975 will permit greater recovery of sulfur gases and particulates. The four reverberatory furnaces now utilized will be maintained on a standby basis.

Kennecott completed construction of new converter hoods, duct work, an electrostatic precipitator, and an acid plant at its Hurley, N. Mex., smelter to improve control of smelter emissions. Production was adversely affected for a period of time during installation of the new equipment and adjustment to new operating procedures. At the McGill, Nev., smelter a 750-foot stack to improve dispersion of effluents and an air quality monitoring system was completed. Also engineering for a sulfuric acid plant was underway with construction scheduled to start in the second quarter of 1975. At the Hayden, Ariz., smelter throughput was reduced due to roaster and furnace equipment failures and problems associated with learning to operate new air pollution control facilities installed in 1973. At the Garfield, Utah, smelter a 1,200-foot stack, the tallest in the industry, was completed as part of an extensive construction project for improved environmental controls to be completed in 1977. Also included in the project will be the replacement of existing reverberatory furnaces and converters with a continuous smelting-converting unit developed by Noranda and also construction of an additional sulfuric acid plant.

Phelps Dodge made substantial progress in construction of a new copper smelter in Hidalgo County, N. Mex., with completion scheduled for third quarter of 1975. Cost of the smelter project, including townsite, is estimated at $200 million. It will be the first smelter in the United States to utilize the flash smelting process. Initially the facility will have the capacity to treat about 1,400 tons of concentrates daily, equivalent to about 100,000 tons of anode copper annually. All of these concentrates would be provided by the company's Tyrone mine. Tentative agreement was reached to smelt concentrates from the Cyprus Mines Corp. expanded Bagdad, Ariz., mine, beginning in 1978 which will require additional construction to increase the smelter capacity. At the Morenci, Ariz., smelter, a new reverberatory furnace, equipped with waste heat boilers and electrostatic precipitators to remove particulates from furnace gases, went into operation in August, but due to startup problems did not operate at capacity until later in the year. Smelter production was hampered throughout the year while hoods and flues were being installed at each of the nine converters. At the Ajo, Ariz., smelter, new emissions control facilities, including a 600-ton-per-day sulfuric acid plant, were completed.

Magma Copper Co. replaced a manually operated anode casting system with a computer-controlled anode casting system at the San Manuel smelter. The new system lowers costs by producing more closely controlled and uniform weight anodes which improves refining efficiencies and reduces the generation of anode scrap. A new sulfuric acid plant brought onstream in the fourth quarter, in conjunction with use of intermittent production controls at the smelter, when required by atmospheric conditions, will enable Magma to meet ambient air quality standards in effect. An auxiliary plant has been constructed to neutralize any acid produced in excess of sales.

Inspiration Consolidated Copper Co. completed a construction program which provided new production facilities including an electric furnace to replace the reverberatory furnace, new siphon-type converters, and a new sulfuric acid plant. Startup problems took much longer and presented more problems than expected. Repairs, necessitated by a leak which developed in one wall of the electric furnace, caused suspension of operations for 1 month. A strike caused a 40-day delay. By yearend, production at both the smelter and acid plant was improved but was still below rated capacity.

Refined Production.—Production of refined copper from primary materials decreased 11% to 1.65 million tons, the smaller quantity reflecting strikes at most producing units during portions of July and August. Refined copper produced from scrap was 496,908 tons compared with 465,123 tons in 1973. Total production of refined copper in the United States was 2.15 million tons, derived 77% from primary and 23% from scrap sources.

ASARCO continued construction on a new refinery of 420,000 tons of annual copper capacity at Amarillo, Tex. Some sections of the refinery will be brought into operation by mid-1975 and the entire facility is scheduled for completion during the first quarter of 1976. The Amarillo refinery will replace ASARCO's Baltimore refinery which will be phased out after 1975. Together with the necessary infrastructure and related facilities the project was estimated to cost on the order of $175 million and will employ 700 people. At the Tacoma, Wash., refinery of ASARCO a new plant was constructed to recover nickel salts from the copper electrolyte, replacing the existing plant built in 1917.

An expansion project by Anaconda to increase capacity at its Great Falls, Mont., refinery by 38% to 42 million pounds per month will be fully operational by March

1975. A modified power supply is incorporated in the expansion project which could provide an additional refining capacity increase of up to 3 million pounds per month.

Copper Sulfate.—Copper sulfate was produced from primary and/or secondary metal by companies with plants located as follows:

Company	Plant location
The Anaconda Company	Great Falls, Mont.
Chevron Chemical Co	Richmond, Calif.
Cities Service Co	Copperhill, Tenn.
Phelps Dodge Refining Corp	Laurel Hill, N.Y. El Paso, Tex.
Van Waters & Rogers Inc	Wallace, Idaho. Midvale, Utah.

Copper sulfate production declined 3% to 42,092 tons, a reversal of the upward trend of the past 2 years. Shipments plus consumption by producing companies exceeded production by 1,506 tons and ending stocks were drawndown to 3,074 tons, the lowest yearend level since 1959. Of the total 43,598 tons shipped, producers' reports indicated that 18,972 tons was for agricultural uses, 23,840 tons was for industrial uses, and 786 tons was for other uses.

Byproduct Sulfuric Acid.—Sulfuric acid was produced at 12 copper smelters from the sulfur contained in offgases, and output in 1974 increased for the seventh consecutive year from 1,088,300 in 1973 to a record 1,277,400 tons, on a 100% acid basis. Copper smelters at Ajo, Ariz., Hurley, N. Mex., Miami, Ariz., and San Manuel, Ariz. had initial production from new sulfuric acid plants in 1974. In addition, sulfuric acid plants were under construction at the McGill, Nev., smelter and at the new Hidalgo County, N. Mex., smelter. The indicated total capacity to produce acid at yearend was substantially greater than 1974 output.

SECONDARY COPPER AND BRASS

Domestic recovery of copper in all forms from all classes of purchased scrap totaled 1.34 million tons in 1974, a 2% decrease from the 1973 total. Recovery from copper-base scrap declined from 1.36 million to 1.32 million tons. Brass mills accounted for 42% of the recovered copper, primary producers for 32%, and secondary smelters for 21%. The remaining 5% was reclaimed at chemical plants, foundries, and manufacturers.

Consumption of purchased copper-base scrap in 1973 was 1.78 million tons consisting of 62% new scrap and 38% old scrap. Of the major categories of copper and copper-alloy products derived from scrap, the output of unalloyed copper increased 6% to 513,300 tons while production of brass mill products and brass and bronze ingots each decreased 8% to 702,700 tons and 261,600 tons, respectively.

CONSUMPTION

Consumption of refined copper was 2.19 million tons, a 10% decrease from the 1973 record high. The relatively high level of consumption in the first half of the year was substantially lower in the second half as a reflection of the slump in construction, automobile production, and other areas of the economy which consume copper. Wire mills accounted for 67% of refined copper consumption, brass mills for 31%, and all other categories for the remaining 2%.

Apparent withdrawals of primary refined copper on domestic account, excluding the supply component of approximately 252,000 tons released from the Government stockpiles, was 1.78 million tons compared with 1.90 million tons in 1973.

STOCKS

Stocks of refined copper at primary producers increased from 37,000 tons at the start of the year to 43,000 tons by the end of April, dipped to 24,000 tons at the end of June, then rose to 101,000 tons by yearend with much of the increase in November and December. This was the largest yearend stock level since 1970. Fabricators' stocks of copper in all forms increased from 419,000 to 496,000 tons during the year.

PRICES

The domestic producer price for refined copper was restricted to 68 cents per pound for cathodes until removal of price controls at the end of April after which the price advanced to 80 cents on May 1 and to 85 cents on June 1; then, reflecting changing market conditions, the price was reduced to 79 cents on September 17, to 75 cents on October 16, and to 72 cents on November 26. The cathode price was reduced to 68 cents by one producer, effective December 27, 1974, and by the other producers, effective January 3, 1975. Electrolytic wire bar quotations were 0.625 cent to 2 cents above quotations for cathode copper. Average quoted prices for electrolytic copper was 77.3 cents per pound for 1974 compared with 59.5 cents for 1973.

Prices on the London Metal Exchange (LME) escalated from a monthly average of 92.1 cents per pound for January to 137.5 cents for April with an alltime high daily quotation of 152 cents on April 1. After April there was a rapid descent of LME prices to an average 58.4 cents for December. The average for the year was 93.1 cents compared with 80.9 cents for 1973.

FOREIGN TRADE

Imports of copper were an increased component of supply in 1974 as imports of unmanufactured copper, excluding alloyed copper scrap, were 608,600 tons compared with 420,500 tons in 1973 while exports decreased from 277,600 to 198,100 tons. The largest trade category, refined copper, had a 55% increase in imports to 313,600 tons and a 33% decrease in exports to 126,500 tons. Imports of blister copper were 207,800 tons compared with 154,100 tons in 1973. The other import categories of ore, concentrates, matte, and unalloyed copper scrap totaled 87,200 tons and the other export categories of ore, concentrates, matte, blister, unalloyed scrap and ash and residues totaled 71,600 tons.

Exports of alloyed copper scrap, in gross weight, were 118,200 tons compared with 110,400 tons in 1973. Imports of alloyed copper scrap were 15,900 tons, gross weight, or 10,500 tons, copper content.

WORLD REVIEW

World mine production of copper attained 8.10 million tons in 1974, an increase of 3% with the most significant production increases coming from Chile, Poland, and Australia. The United States continued to lead the world in mine production with 20% of the total, followed by Chile 12%, Canada 11%, the U.S.S.R. 10%, Zambia 9%, Zaire 7%, Australia 3%, Philippines 3%, Peru 3%, and Poland 3%.

Stimulated by record high LME copper prices, the incentive for increasing mine production in the first half of 1974 was high. As the full impact of a worldwide economic recession hit the copper industry in the second half of the year, demand and metal prices dropped sharply. As producer stockpiles of copper began to buildup substantially by late 1974 a number of U.S. and Japanese copper companies began instituting mine and refinery production cutbacks of up to 20%. The Japanese copper industry, which was particularly hard hit by the economic downturn, was unable to market refined copper in the weakened Japanese domestic economy. The Japanese copper industry then began to negotiate with suppliers to reduce deliveries of ores and concentrates previously contracted for under long-term agreements and to resell substantial quantities of refined copper on the world market further depressing prices. In response to these events the Conseil Intergouvernemental des Pays Exportateurs de Cuivre (CIPEC), comprised of Chile, Peru, Zaire, and Zambia, met in Paris in November and agreed to cut all copper exports by 10% effective December 1, 1974.

World stocks of refined copper as reported by the World Bureau of Metal Statistics, were builtup from approximately 690,000 to 996,000 tons during the year. The stocks included producer, consumer, and merchant inventories of 245,000 tons of refined copper in the United States, 189,000 tons in Japan, and 192,000 tons combined between West Germany, France, and the United Kingdom plus 139,000 tons held in LME warehouses and 43,000 tons in Commodity Exchange Inc. (COMEX) warehouses in the U.S. The total world stock level represented the equivalent of 1.3 months of average demand of the world market economies for copper in 1974.

Argentina.—Cía. Minera Aguilar, S.A., the Argentina subsidiary of St. Joe Minerals Corp., continued development of a significant porphyry copper deposit with reserves currently estimated at 550 million tons of 0.65% copper and 0.015% molybdenum. Engineering studies, cost estimates, plans for smelter, mill and pit design, and studies of transportation access began or were completed in 1974. Development discussions with the Argentine Government were in progress with a proposed 1980 startup for a 75,000- to 100,000-ton-per-year copper operation being considered. The Pachon deposit is located in one of the most difficult access areas in the Andean range, 2 miles from the Chilean border. For most of the year the region is covered with 10- to 15-foot snow drifts.

Australia.—Mount Isa Mines, Ltd., operated its copper-lead-zinc-silver mine at Mount Isa and a copper smelter at Townsville to produce a record 168,000 tons of blister and 144,000 tons of refined copper for the fiscal year ending June 30, 1974. This output was the first year's achievement of the rated productive capacity of 170,000 tons resulting from an expansion program completed in 1973. The near capacity production was attained despite a cutback during February and March 1974 because of a 5-week closure of the flood-damaged Mount Isa to Townsville railroad which halted movement of supplies and concentrates. Reported reserves were 156 million tons of 3% copper.

Mount Lyell Mining and Railway Co., Ltd., a subsidiary of Consolidated Gold Fields Ltd., for the year ended June 30, 1974, produced 26,800 tons of copper in concentrate from 2.57 million tons of ore grading 1.19% copper mined and milled at its Tasmania operation. Surface ores accounted for 22% of total production during this period with the mining of the remaining surface ore in Crown Three open cut scheduled to be completed in late 1974. The transition towards full underground mining operations progressed smoothly during the year with the Prince Lyell section, the major underground ore body, accounting for 46% of total production. Reserves in all ore zones were estimated at 33 million tons of measured ore grading 1.47% copper and 11.7 million tons of indicated ore grading 1.40% copper.

The Woodlawn copper-zinc-lead-silver deposit near Tarrago, New South Wales, a 50/50 joint venture of Phelps Dodge Corp., and St. Joe Minerals Corp. (Jododex) was delayed by additional metallurgical pilot plant test work required by the refractory nature of the ore. Earlier feasibility studies are being updated on the basis of new pilot plant results and changing economic and political conditions in Australia. Ore grade material intersected during 1974 drilling gave considerable promise that underground mining may follow extraction of the originally announced open pit material.

Cobar Mines Pty., Ltd., fully owned by BH South Ltd., continued development of the significant massive sedimentary copper and copper-zinc deposits in central New South Wales. The mineralization occurs in lenses up to 3,300 feet wide in seven main ore bodies over a 10-mile strike length. The CSA mine, currently in production north of Cobar has estimated reserves of over 18 million tons grading 1.9% copper. In 1974 the two main shafts were deepened to 3,300 feet. The mill treated 727,500 tons of ore yielding 12,700 tons of copper contained in 50,860 tons of concentrates. An open stope and cut and fill stope mining method is in operation. During the year work was nearly completed on a 3,300-foot deep shaft south of the town of Cobar to give exploration and development access to the Chesney, New Occidental, Dapville, Gladstone, New Cobar, and Great Cobar ore bodies.

Kanmantoo Mines Ltd., in Kanmantoo, South Australia, also held by BH South Ltd., completed its second full year of production. Production for the fiscal year ending June 30, 1974, was 7,900 tons of copper contained in 35,600 tons of concentrate recovered from 1,041,100 tons of 0.82% copper sulfide ore milled. Drilling in 1974 disclosed ore bodies of similar grade and type as those at the open pit, which will be mined by underground methods when the open pit is mined out about 1982.

Construction of a plant to treat stockpiled oxide ores is expected to be completed by March 1975. Treatment of the stockpiled oxide ore, now in excess of 560,000 tons, will take approximately 3 years.

Peko-Wallsend Ltd., operated a copper-gold mine at Mount Morgan, Queensland, and the Tennant Creek copper-gold-bismuth mines in the northern territory. At the Tennant Creek operations the Warrego concentrator, rated at a capacity in excess of 770,000 tons per year, produced 16,300 tons of contained copper in 740,000 tons of ore treated. Ore reserves at the five Tennant Creek mines were over 8 million tons grading an average 3% copper. During the fiscal year ending July 9, 1974, Mount Morgan produced 10,600 tons of contained copper from 1.4 million tons of ore treated. Remaining reserves were estimated at less than 4 million tons grading 0.75% copper. The new smelter at Tennant Creek also came into full operation during the year. A pilot plant based on a process patented jointly by the University of Queensland and the company for the economic recovery of high-purity copper from leach liquors has been successfully operated at the Mount Morgan mine. The material treated was flue dust from the old smelting operations plus a test sample of current Tennant Creek flue dust. The process leaves a bismuth-copper residue in a form acceptable for direct smelting of the bismuth. In late December 1974 the company suspended all copper mining and smelting operations at Tennant Creek for economic reasons.

Discovery of a new copper deposit at Golden Grove, near Yalgoo in Western Australia, was reported by a consortium including AMAX, Inc., and the Electrolytic Zinc Co. of Australasia Ltd. The group has proven reserves to 1,800 feet of 11 million tons of 3.5% copper. An estimated $90 million investment is required to develop the planned mine, mill, and associated infrastructure.

Botswana.—Bamangwato Concessions, Ltd. (BCL), brought its Selebi-Pikwe nickel-copper mining and smelting project into production in December 1973 with initial mining of ore, and commissioned the surface treatment plant in February 1974. However, technical operating problems remained to be solved and the rated capacity of about 17,000 tons of copper and 19,000 tons of nickel in copper-nickel matte are not expected to be attained before early 1976. Ownership of BCL is 15% by the Government of Botswana and 85% by Botswana Roan Selection Trust, Ltd. (BRST), which in turn is owned 40% by the public and about 30% each by AMAX and the Anglo American Corp./Charter Consolidated Group.

Brazil.—In November 1974 the Brazilian Government nationalized copper production in Brazil with the takeover of the Caraiba deposit in the northeastern State of Bahía. Caraiba with an estimated 45 million tons of 1.3% copper ore is the most important copper reserve in Brazil. The mining and transportation operations of the former privately held Caraiba Metalis, S.A., will now be handled by the State-run Companhia Vale do Rio Doce (CVRD). Commercial and administrative operations will be run by Financiamentos de Insumos Basicos, S.A. (FIBASE), a subsidiary of the National Development Bank. New feasibility studies on developing an open pit operation and a smelter to produce 35,000 to 50,000 tons per year of contained copper from Caraiba are continuing.

Canada.—Mine production increased 2% in 1974 to a record high 928,550 tons of recoverable copper. Smelter output increased 8% to 591,990 tons and refinery production 12% to 616,329 tons of copper. Mine production increased in nearly all Provinces in 1974 except for British Columbia where production dropped 7% to 327,221 tons. British Columbia barely retained its position as the leading copper-producing Province with 35% of the total followed by Ontario with 34%, Quebec 17%, Manitoba 9%, and the remaining Provinces 5%.

In action which could have significant impact on future Canadian copper production and reserve levels, many companies are reported to have curtailed exploration activities and expansion programs in 1974 in British Columbia and to a lesser extent in Saskatchewan, Manitoba, and Ontario in reaction to increased taxes and royalties that have been set up by some Provinces. The new provincial taxes are in addition to Federal levies and created a double tax burden for the mining industry. A serious shortage of skilled mining and trades personnel also affected production levels at many Canadian copper operations during the year.

Falconbridge Nickel Mines Ltd. in 1974 produced copper from nine nickel-copper mines in Sudbury, Ontario, and Manibridge, Manitoba, and from five copper-zinc, copper, and iron-copper mines in Lake Dufault and Opemiska, Quebec, Sturgeon Lake, Ontario, and Tasu Harbor, British Columbia. Concentrates from the nickel-copper operations were processed at the company smelter in Sudbury and those from the other copper-zinc operations at the Noranda Mines Ltd. smelter at Noranda. Total metal deliveries in 1974 from all operations included 55,500 tons of copper, a decrease of 18% from those of 1973. Ore reserves at yearend at these two operations were 91 million tons averaging 1.4% nickel and 0.68% copper. The Lake Dufault Div. of Falconbridge Copper Ltd. milled 553,200 tons of 2.38% copper in 1974 to produce 12,230 tons of copper in concentrate, 35% less than in 1973. The decrease was attributed to a lower grade of ore treated. The Norbec mine was closed effective December 31, 1974, for economic reasons. Reserves at yearend were 2.5 million tons of ore grading 3.2% copper and 4.0% zinc. The Opemiska Division milled 927,000 tons of 1.85% copper in 1974 to produce 16,230 tons of copper in concentrate. The 25% cut in production was attributed to lower grade ore treated and to a shortage of skilled mine workers.

Plant construction at the new Cooke mine was completed and the shaft sinking reached 1,029 feet. Reserves at yearend were 6.4 million tons of 2.35% copper ore. The Sturgeon Lake Mines Ltd. open pit and concentrator came into production in September at a planned rate of 200 tons per day with 82,600 tons of ore grading 2.05% copper milled in the first 4 months of operation. Production of copper totaled 974 tons. Ore reserves at yearend were 2.2 million tons with an average grade of 2.80% copper, 10.19% zinc, 1.42% lead, 5.82 ounces of silver per ton and 0.021 ounce of gold per ton. In addition to the above, Falconbridge's Wesfrob mine, in Tasu Harbor, British Columbia, produced 2,300 tons of copper in concentrate in 1974 as a byproduct of the open pit iron operation.

Texasgulf Canada Ltd. (formerly Ecstall Mining Ltd.) mined 3.72 million tons of ore in 1974 up 3% over 1973 from the Kidd Creek mine near Timmins, Ontario. Production was about 74% from the open pit and 26% from underground. The mine yielded 231,700 tons of a 25% copper concentrate and 9,500 tons of a copper-silver concentrate during the year. The Kidd Creek zinc-silver-copper mine is one of the largest, mixed base metal mines in Canada having yielded from the start of operations in 1966 through the end of 1974 a total of 28.6 million tons of ore averaging 1.56% copper, 9.66% zinc, 4.3 ounces of silver per ton, and 0.38% lead. At the end of 1974 unmined reserves above the 2,800-foot level were estimated at 94 million tons of comparable grade ore. Exploration below 2,800 feet during the year indicated the ore body continues to at least 5,000 feet. Drilling indicated one 1,100-foot-long intersection assaying 3.2% copper with a true width of over 700 feet. The copper grade is increasing with depth and the zinc grade decreasing. Texasgulf is proceeding with plans to increase the mine production rate from 3.6 to 5.0 million tons per year. The expansion is scheduled to include a $200 million copper smelter and refinery complex with a capacity of 130,000 tons of copper per year. The Government-owned Canada Development Corp. acquired a 30% interest in Texasgulf Canada Ltd. during the year.

The International Nickel Co. of Canada Ltd. (INCO) mined 22 million tons of ore with an average grade of 1.39% nickel and 0.97% copper from 16 mines in Ontario and Manitoba in 1974 compared with 19.7 million tons of ore with an average grade of 1.41% nickel and 0.98% copper in 1973. Deliveries of copper metal from the Copper Cliff refinery increased 12% to 183,595 tons. At yearend INCO estimated that proven ore reserves in Canada were 414 million tons containing 1.62% nickel and 1.01% copper. In January production from the Crean mine was resumed on a regular basis. In December operations at the Clarabelle open pit mine in Sudbury ceased pending development of an extension to the mine. Development work on the Levack West underground mine also continued with a 4,000-ton-per-day mine production schedule expected to start in 1975.

Noranda Mines Ltd. had a full or partial interest in the treatment of 48.5 million tons of ore containing 226,300 tons of contained copper from 14 copper and zinc-copper mines in Quebec, British Columbia, Ontario, and New Brunswick. Shortages of skilled miners and tradesmen continued to hamper a number of Noranda's operations during the year. The company's two copper smelters at Noranda, Quebec, and Gaspé Copper in Murdochville, Quebec, in 1974 treated 938,000 tons of concentrates from Noranda operations and 929,300 tons of custom material from 29 other Canadian copper mines and from overseas. The 1.9 million tons of total material treated yielded 338,700 tons of copper contained in anodes, 10% more than in 1973. The Noranda smelter accounted for 79% and Gaspé 21% of anode production. Canadian Copper Refineries Ltd. (CCR) in Montreal East, Quebec, operated by Noranda, is one of the world's largest copper refineries with a rated annual capacity of 480,000 tons. In 1974 refinery production increased 11% to 427,000 tons of copper. CCR processes the output of the Noranda smelters, the Flin Flon smelter of Hudson Bay Mining & Smelting Co., Ltd. and from imported and some secondary sources.

Noranda's Horne Div. in Noranda, Quebec, produced 477,400 tons of ore averaging 2.57% copper and 0.147 ounce of gold per ton. The mill treated 390,000 tons of sulfide ore and 235,000 tons of smelter slags producing 71,500 and 57,300 tons of copper concentrates, respectively. Reserves of 400,000 tons of 1.74% copper at the Horne mine are expected to be depleted by 1976. Plans to bring the Magusi-New Insco ore bodies, with combined reserves of 3.2 million tons with an average grade of 3.1% copper, into production are underway. The Geco Div. in Manitouwadge, Ontario, produced 1.8 million tons of ore grading 1.72% copper, 4.72% zinc, and 1.56 ounces of silver per ton. Concentrates produced contained 29,200 tons of copper. Reserves at yearend were 28.6 million tons grading 1.87% copper, 3.69% zinc, and 1.59 ounces of silver per ton. The Bell Copper Div. in Granisle, British Columbia, mined 4.5 million tons of ore grading 0.52% copper in 1974. Concentrate output of 79,700 tons contained 20,800 tons of copper. Yearend reserves for the original pit design were over 34 million tons of 0.49% copper and 0.012 ounce of gold per ton at a waste to ore stripping ratio of 0.5 to 1. Studies indicate a future potential to expand reserves to 79 million tons at a 1.5 to 1 stripping ratio.

Gaspé Copper Mines (Noranda) produced 1.23 million tons of 1.09% copper ore and 43,500 tons of concentrate containing 11,530 tons of copper from the Needle Mountain mine and 9.32 million tons of 0.55% copper ore and 159,300 tons of concentrate containing 39,800 tons of copper from the Copper Mountain mine. Reserves at the two mines were, respectively, 23 million tons of 1.33% copper and 212 million tons of 0.38% sulfide copper plus 34 million tons of 0.45% oxide copper.

Brenda Mines Ltd. (50.9% Noranda) located in Peachland, British Columbia, operating one of the lowest grade porphyry copper mines in the world produced 9.55 million tons of ore averaging 0.186% copper and 0.051% molybdenum. In addition, the mining operation stockpiled 4.4 million tons of lower grade ore and removed 2.7 million tons of waste. Metal recoveries were 85.9% for copper in 51,365 tons of concentrates and 78.5% for molybdenum in 6,811 tons of leached concentrate. Yearend reserves were 127 million tons of 0.18% copper and 0.046% molybdenum.

Mattagami Lake Mines (43% Noranda) operated the Mattagami Lake mine in Quebec and the Mattabi mines in northwestern Ontario and began development work on a new underground mine at Lyon Lake in the Sturgeon Lake area of Ontario. Ore treated at Mattagami amounted to 1.4 million tons averaging 7.5% zinc, 0.62% copper, 0.88 ounce of silver per ton, and 0.017 ounce of gold per ton which yielded 27,150 tons of copper concentrate with a copper recovery of 76%. Remaining ore reserves totaled 12 million tons grading 8.7% zinc, 0.66% copper, 0.98 ounce of silver per ton, and 0.015 ounce of gold per ton. At Mattabi the concentrator treated 1.14 million tons of ore grading 0.91% copper yielding 8,600 tons of contained copper in concentrate. Ore reserves were over 11 million tons of 6.51% zinc, 0.74% copper, 0.64% lead, 2.42 ounces of silver per ton, and 0.007 ounce of gold per ton. Planning for the development and mining of the underground portion of the ore body is continuing. Reserves at the Lyon Lake deposit were an estimated 3.1 million tons of 6.2% zinc, 1.15% copper, 0.60% lead, 3.3 ounces of silver per ton, and 0.11 ounce of gold per ton.

Placer Development Ltd. (33% Noranda) operated the Craigmont mine in Merritt, British Columbia, and the Gibralter mine at McLeese Lake, British Columbia, during the year. The major porphyry copper open pit Gibralter mine milled 13.4 million tons of ore grading 0.40% copper. With a recovery rate of 84%, 45,123 tons of copper were produced in 166,800 tons of concentrate. Overall copper production decreased 26% due to the lower grade mined, a chronic shortage of qualified personnel to adequately maintain equipment and a 2-week wildcat strike in May. Mining in Stage 1 of the Gibralter east pit was completed in August when operations were transferred to the Granite Lake pit. In preparing the Granite Lake pit over 3 million cubic yards of overburden were removed and 850,000 cubic yards of silt were dredged from the lakebed. Overburden stripping commenced on the Pollyana ore zone and 658,000 cubic yards were removed by yearend. Reserves were estimated at 319 million tons at a 0.25% cutoff and an average grade of 0.36% copper. At Craigmont 1.52 million tons of ore grading 1.48% copper were milled. The 75,100 tons of concentrates produced contained 21,741 tons of copper for a metal recovery of 96.6%. Ore reserves of 8.6 million tons of 1.84% copper are sufficient to maintain operations at the 1974 level for 4 to 5 years.

Hudson Bay Mining & Smelting Co., Ltd. operated nine mines in the Flin Flon-Snow Lake area, Manitoba. Production at the Osborne Lake mine was interrupted by the considerable deeper level development work carried out during the year. Approximately 1.57 million tons of ore with an average grade of 2.4% copper were mined and milled to produce approximately 34,400 tons of copper in concentrates, a decrease of 16%. Development work on the access decline, underground services, and the 2,000-foot ore conveyor belt at the new Centennial mine were completed during the year with shaft-sinking scheduled to begin in January 1975. Construction of road, powerline, and surface mine buildings at the new Westarm mine were also completed with shaft-sinking scheduled to begin in April 1975. Total ore reserves at yearend were about 18 million tons grading 2.89% copper, 2.7% zinc, 0.0033 ounce of gold per ton, and 0.50 ounce of silver per ton. As a result of amendments to the British Columbia Mining Royalties Act, Hudson Bay and its partners Kennecott and Cominco Ltd. discontinued further exploration and development work on Stikine Copper Ltd.'s remote property in northwestern British Columbia. Stikine is reported as having impressive tonnage and grade for a porphyry-type copper deposit.

At Hudson Bay's Flin Flon copper smelter a new anode casting plant began operating in March to completely replace blister casting. The first of two new waste-heat boilers and a new stack to improve the handling of smelter waste gases became operational during the year. The smelter produced 54,418 tons of metal contained in blister and anode copper with 59% coming from Hudson Bay feed and 41% from purchased concentrates.

Lornex Mining Corp. Ltd. operated an open pit copper-molybdenum mine in the Highland Valley of British Columbia and produced 64,014 tons of copper and 2,017 tons of molybdenum in concentrate. The company delineated major additions to ore reserves at the Lornex property, which under normal economic conditions and reasonable tax and regulatory conditions would support an expansion of the operation.

Anaconda Britannia Mines, Ltd., discontinued operations at its mine in British Columbia, effective November 1, owing to a combination of limited ore reserves, rising costs, and reduced copper prices. The operation had been producing at an annual rate of approximately 6,000 tons of copper in concentrates.

The Caribou copper mine near Bathhurst, New Brunswick, a joint venture of The Anaconda Company and Cominco, suspended operations October 1 because of exhaustion of minable open pit copper ore. The Caribou mill had been rated at a capacity of 1,000 tons of ore per day to process the 3.4% average grade of ore mined.

Similkameen Mining Co. Ltd., a subsidiary of Newmont Mining Corp., operated its open pit mine near Princeton, British Columbia, and output for the year was 21,100 tons of copper in concentrate obtained from milling 5.1 million tons of 0.48% copper ore. Expansion of the concentrator was under construction to permit milling 7,000 tons per day of material grading about 0.25% copper which is now being mined and stockpiled. Ore reserves at yearend were estimated at 61 million tons averaging 0.53% copper.

Utah International, Inc. shipped approximately 45,500 tons of copper and 45,000 ounces of gold in concentrate from its Island Copper mine on the northern end of Vancouver Island in British Columbia. The mill output of copper was 6% lower than in 1973 and 21% below the design capacity of 57,500 tons of copper in concentrates annually. The lower production was due chiefly to a 7-week-long strike in August and September.

The Granduc mine of Granduc Operating Co., north of Stewart, British Columbia, produced 31,900 tons of copper in concentrate from 2.7 million tons of ore grading 1.23% copper. Re-examination of ore reserves in the light of production costs and anticipated copper prices resulted in a reduction of minable reserves from 33 million tons of 1.64% copper at yearend 1973 to 22 million tons of 1.71% copper at yearend 1974. Much of the eliminated reserves were of lower grade material in the undeveloped areas below the 2,100-foot level, which in turn is 500 feet below the haulage level.

Sheritt-Gordon Mines Ltd. operated the Fox, Lynn Lake, and Ruttan Lake mines in Manitoba with a combined output of 50,000 tons of copper in concentrates compared with 35,800 tons in 1973. The increase reflected the first full year of operation at the Ruttan Lake copper-zinc open pit operation in which 3.4 million tons of ore averaging 1.07% copper and 1.68% zinc were milled. At the Fox underground mine, 1.0 million tons of ore averaging 2.10% copper and 1.98% zinc were milled compared with 963,000 tons of 2.01% copper and 2.07% zinc in 1973. Output at the Lynn Lake nickel-copper mine was below expectations with ore milled declining to 432,000 tons assaying 0.87% nickel and 0.43% copper. Reserves at the Ruttan mine are estimated at 46 million tons of 1.45% copper and 1.52% zinc and at the Fox mine at 11 million tons averaging 1.95% copper and 2.07% zinc. At Lynn Lake reserves are adequate for about 5 years but high operating costs make continued operation uncertain.

Patino Mines (Quebec) Ltd., a subsidiary of the Dutch company Patino, N.V., operated or had an interest in five copper-gold mines in Quebec during 1974. Total mill production of 859,000 tons of 1.56% copper was down from the 1973 input of 973,000 tons of 1.62% copper. Metal production in 1974 amounted to 12,900 tons of copper in concentrate, down 16% from 1973. Two months of production were lost because of strike actions during the year. Ore reserves at yearend were 6.4 million tons of 1.74% copper and 0.046 ounce of gold per ton. The associated company Lemoine Mines Ltd. continued with the development of its new underground Bauzan mine located in a swamp 37 miles southeast of Chibougamau. The high-grade volcanogenic massive sulfide deposit contains reserves of 625,000 tons of 4.5% copper, 10.8% zinc, 2.7 ounces of silver per ton, and 0.138 ounce of gold per ton.

Bethlehem Copper Corp. Ltd. milled 6.3 million tons of ore grading 0.51% copper from open pit mines at Highland Valley, British Columbia, and produced concentrates containing 28,500 tons of copper compared with 33,500 tons in 1973. Exploration confirmed reserves of approximately 30 million tons of 0.45% copper in an extension to the closed Jersey pit and 15 million tons of 0.46% copper in the Iona ore body. Reserves at the operating Huestis pit are 14 million tons giving total reserves of 61 million tons of 0.47% copper available to the mill or enough for about 10 years of operation at the current rate. Development of the 286-million-ton J-A ore body and the adjoining 1-billion-ton 0.48% copper ore body of Valley Copper Mines Ltd., in which Bethlehem has a 20% interest, has been deferred due to adverse economic conditions and new taxing laws. Development of the Maggie ore zone, north of Highland Valley, with indicated reserves of 200 million tons of 0.40% copper, is also being delayed.

Union Minière Canada Ltd., initiated development of its Thierry copper deposit in the Pickle Lake, Ontario region with planned production for the second half of 1976 at an annual rate of 1.4 million tons of ore milled. The project is estimated to cost $85 million. Proven reserves amounted to 13 million tons averaging 1.73% copper, of which 3 million tons are amenable to open pit mining. Exploration work was in progress to further delineate reserves.

Chile.—In its first full year of control the new Chilean Government was instrumental in achieving a record copper production and encouraging a renewed foreign investment climate.

In a major first step, the Government promulgated Foreign Investment Law (DL-600) in July 1974. The new law guarantees foreign investors the right to repatriate the return of capital invested and profits obtained and that taxes as stated in the contracts will not be modified. In a second step Chile settled all litigation and outstanding claims for compensation for the expropriation of privately owned mines by the Allende Government in 1971. Cerro Corp. received an agreement for compensation of $41.9 million for its expropriated interests in Cía. Minera Andina, S.A. In July, Chile agreed to pay Anaconda $253 million, for its interests in the Chuquicamata mine. In October, Kennecott received a net compensation for the takeover of its interests in Sociedad Minera El Teniente, S.A., of $68 million.

In December, Chile reimbursed the U.S. Overseas Private Investment Corp. $18.6 million for insurance payments paid to Anaconda for its expropriated interests in the Exótica mine to conclude all outstanding obligations. In conjunction with these actions Chile began soliciting bids for new foreign investment participation in the further exploration and development of the country's copper resources which at yearend included eight known deposits with estimated combined ore reserves of 4 billion tons with a likely average grade of 0.8% copper. Cutoff date for bids on these deposits is March 30, 1975.

Production for the year increased 23% to 994,400 tons of copper and placed Chile as the world's second largest copper producer behind the United States. Production from the large mines was as follows: Chuquicamata, 393,200 tons compared with 292,400 tons in 1973; El Teniente, 248,500 tons compared with 196,300 tons; El Salvador, 88,200 tons compared with 92,600 tons; Andina, 75,400 tons compared with 61,800 tons; and Exótica, 35,500 tons compared with 35,100 tons.

In the medium and small mine production area, Mantos Blancos increased output 11% to 35,500 tons, Empresa Nacional de Minera (ENAMI) dropped 3% to 78,500 tons, and Disputada doubled production to a more normal level of 28,500 tons of copper.

New equipment expenditures of $28 million were made at the major mines, including the installation of a new reverberatory furnace at El Teniente to help compensate for abandonment of the oxygen converter process installed by Kennecott and the installation of a new pilot solvent extraction plant at Exótica.

Cyprus.—The Cyprus Island Div. of Cyprus Mines Corp. permanently closed its copper mining operations in July following a forced shutdown of operations resulting from Turkish military intervention. Prior to cessation of operations, 3,900 tons of copper in concentrates and precipitates were sold.

India.—Extensive exploration of India's copper resources indicated presently available ore reserves of over 335 million tons containing an average grade of 1.5% copper located in 25 deposits in 5 States. The Khetri copper project in Rajasthan, including a new flash smelter and electrolytic refinery, designed initially to produce 11,000 tons of copper annually began operation in November. Capacity of the project is expected to be increased to 50,000 tons by 1977. Feed for the smelter comes from two new mines, the Khetri (Madhan Kudhan) mine with reserves of 77 million tons of 1% copper and the Kolihan mine with 35 million tons of 2.5% copper.

With the cooperation of a Canadian technical assistance program a feasibility study was begun to assess the viability of developing the Rakha-Roam-Tamapahar deposit in the Singbhum Copper Belt of Bihar. Proven and inferred reserves are reported at 97 million tons of 1.3% copper.

Indonesia.—Freeport Indonesia, a subsidiary of Freeport Minerals Co. and operator of the 11,500-foot-high Gunung Bijih (formerly Ertsberg) copper mine in Irian Jaya, overcame difficult startup problems and reached planned production rate objectives in its second full year of operation. Production of copper for the year increased 73% to 72,100 tons of copper contained in 230,700 tons of concentrates. Copper content of ore mined continued to exceed the average 2.5% copper determined from original drilling. The contract with the Indonesian Government was modified in December discontinuing Freeport's tax holiday and making the company subject to a 30% income tax on operations beginning July 1, 1974, and increasing to 42% after 1983.

Elsewhere in Indonesia, Kennecott and Endeavor Oil Ltd. of Australia are continuing exploration work on a cluster of copper prospects near Gorantalo in the northern arm of the island of Sulawesi.

Iran.—Star Cheshmeh Copper Mining Co., an Iranian Government-owned company, had under development a copper mine and metallurgical complex in southern Iran. Work included stripping operations for the open pit and construction of foundations for the concentrator, smelter, and auxiliary buildings. Design capacity of the complex is approximately 160,000 tons of copper per year with initial production scheduled for mid-1977. Plans include future construction of a refinery to process the smelter output. Ore reserves upon which the project is based are estimated at 400 million tons averaging 1.12% copper. Also substantial reserves of somewhat lower grade ore are indicated to exist in the area.

Malaysia.—The Mamut Mines Development Co., a consortium of Japanese firms in a joint venture with the Sabah Government and other Malaysian interests, continued development of a copper deposit near Mamut, Sabah. Production is scheduled for mid-1975 at a rate of 15,000 tons per day of 0.7% copper ore for an output of 30,000 tons per year of copper in concentrate. The concentrates will be exported to Japan for smelting.

Mauritania.—Société Minière de Mauritanie (SOMIMA) formerly 33.5% owned by Charter Consolidated Ltd. was taken over by the Mauritanian State mining organization rather than have it closed for economic reasons caused by high fuel and transportation costs. In order to maintain local employment the Government will continue to operate the mine. It is felt that the development of the substantial reserves of sulfide ore below the current oxide operations would make the mine more economically viable.

Mexico.—The Mexican Government in an effort to step up the exploitation of the country's substantial copper reserves encouraged the increased equity participation of Mexican private and Government interests in a number of new developments during the year. The Government plan to increase annual copper production to over 300,000 tons by 1977 from the present rate of 90,000 tons would make Mexico a major world producer of copper. The Mexican Government also warned during the year that all mining concessions that are not worked within a reasonable period of time will be confiscated.

Industrial Minera Mexico, S.A. (formerly ASARCO Mexicana, S.A.), increased the output of blister copper 2% to 37,900 tons. In April, ASARCO completed the sale to Mexican investors of 15% of the stock of ASARCO Mexicana, S.A., thus reducing its equity to 34%.

Compãnía Cuprifera La Verde, S.A. (formerly Minas Del Otono, S.A.) was created in October to develop the La Verde copper deposit at Gabriel Zamora, Michoacan, 200 miles west of Mexico City. Lytton Minerals Ltd., a Hudson Bay subsidiary, holds a 48% interest in the new company with the balance shared equally between the Government, Comision de Fomento Minero, and the privately held Mexican company Sociedad de Fomento Industrial, S.A. de C.V. Ore reserves at La Verde are estimated at 81 million tons of 0.7% copper. A $101 million investment is planned to develop an open pit mine and a 16,500-ton-per-day milling operation by 1978 with a later expansion to 22,000 tons. The annual production of metal in concentrates is projected at 37,500 tons of copper, 14,000 ounces of gold, and 400,000 ounces of silver. Construction is scheduled to start around mid-1975.

Compañía Minera de Cananea operated the Cananea mine and smelter to produce 44,373 tons of copper compared with 45,412 tons in 1973. Production was hampered by labor problems and some mechanical breakdowns. An expansion program designed to achieve an output of 70,000 tons of copper in 1976 was also adversely affected by labor problems and delays in deliveries of materials.

The Government intervened to speed up the development of the Santa Rosa and Pilares copper deposits in the Nacozari region of the State of Sonora by forming a new company, Cobre de Sonora, S.A. de C.V. The joint venture will be 70% owned by the Mexican Government and Mexican nationals, including Minera Lampazos (51%), Comision de Fomento (13%), and the Banco Nacional de Mexico and others (6%), with 26.25% held by The Anaconda Company and 3.75% by Phelps Dodge. Cobre de Sonora planned to invest $128 million by 1976 to construct a 15,000-ton-per-day concentrator to treat the estimated 143 million tons of 0.83% copper and associated silver and molybdenum ore. An annual output of 37,000 tons of copper in concentrates is planned. Concentrates will be shipped to a smelter-refinery facility planned for the nearby La Caridad development.

Mexicana de Cobre, S.A., 44% owned by the Mexican Government, started development of the La Caridad porphyry copper pit mine in Sonora. The 66,000-ton-per-day mill will be followed by installation of a smelter and refinery with a planned capacity of 140,000 tons of copper per year by 1978. Investment costs are currently $550 million. Ore reserves are reported at 760 million tons of 0.76% copper and 0.16% molybdenum.

Pakistan.—The Government controlled Resource Development Corp. continued active exploration of the Saindak porphyry copper deposit in the Chagai District of Baluchistan in southwestern Pakistan. The deposit discovered earlier by a United Nations Development Program-Government exploration team contains ore reserves estimated at 275 million tons of 0.5% copper plus a significant molybdenum content.

Panama.—Canadian Javelin Ltd. received and accepted letters of intent from a group of six British, Canadian, and Japanese companies to form a consortium to finance and develop the Cerro Colorado copper concession. Final establishment of the consortium, however, is pending approval of the project by the Government of Panama, with whom negotiations on long-term exploitation contract terms are continuing. Plans called for an 88,000-ton-per-day production operation to be completed in 4 years at an estimated cost of $700 million. Results of the diamond drilling exploration program completed on the concession during the year established the existence of approximately 1 billion tons of proven reserves with an average grade of 0.6% copper.

Papua New Guinea.—Bougainville Copper Pty., Ltd., controlled 53.6% by Conzinc Riotinto of Australia Ltd. (CRA), 20% by the Government of Papua New Guinea (PNG), and 26.4% by the public, milled 33.2 million tons of ore grading 0.70% copper and 0.03 troy ounce of gold per ton. Recovery and concentrate grade improved, despite a slight fall in head grade, to 706,000 tons of 28.73% copper concentrate yielding 203,000 tons of contained copper. Estimated ore reserves in the Panguna ore body at the end of 1974 were approximately 959 million tons of ore averaging 0.47% copper and 0.016 troy ounce of gold per ton. Concentrates from Bougainville are shipped to Japan, West Germany, and Spain for processing. In December at the request of overstocked Japanese smelters, CRA agreed to reduce deliveries of concentrates to Japan by 15%.

Exercising its new powers of self-government prior to full independence from Australia in 1975, the PNG Government requested a renegotiation of the 1967 Bougainville Copper Agreement with CRA. The new agreement approved in December 1974 terminated the tax exempt period, the 20% tax exemption on mining income, and the accelerated depreciation provisions previously granted Bougainville Copper and was set up to give the PNG Government the "lion's share" (70%) of excess profits over and above a reasonable return upon funds placed by a foreign investor at risk in a project. Additional provisions included increased cooperation on environmental matters, increased liaison with Bougainville Provincial Government, the establishment of normal controls such as import duties and tarriffs by the PNG Government and no further exploration outside the mine area without Government approval.

Exploration work on the Ok Tedi deposit located in the Star Mountain region of northwest Papua near the Indonesian border was halted during the year as negotiation on the terms of development and investment between the exploration license holder Kennecott Copper Corp. and the PNG Government continued. The Mount Fubilan portion of the deposit is one of the geologically youngest (1.2 million years) porphyry copper deposits yet discovered. The deposit consists of a central orthoclase-rich intrusion which contains most of the disseminated copper mineralization, a number of closely associated peripheral mineralized skarn bodies with high copper grades in massive magnetite zones, and a massive sulfide body with moderate copper grades in pyrite and pyrrhotite zones. An oxidized capping up to 1,000 feet thick is developed over the deposit.[8]

---

[8] Bamford, R. W. The Mount Fubilan (Ok Tedi) Porphyry Copper Deposit, Territory of Papua and New Guinea. Econ. Geol., v. 67, No. 8, 1972, pp. 1019–1033.

Preliminary drilling suggests an estimated reserve of 275 million tons of 0.6% to 0.9% copper. The remote location of the Ok Tedi deposit, however, requires establishment of additional ore reserves before development can be considered. Work also continued on the Frieda River porphyry copper prospect in southwestern New Guinea. The exploration license holder Mount Isa Mines, Ltd. signed an agreement with a consortium of four Japanese companies which will earn a 40% interest in the project by spending $5 million over the next 5 years on exploration, testing, and engineering work.

Peru.—Empresa Minera del Centro del Perú (Centromin), the State mining agency, operated six underground and one open pit copper-producing mines, including the former Cerro Corp. properties, expropriated January 1, 1974. Centromin also operated the smelter-refinery complex at La Oroya previously owned by Cerro. An expansion program is planned to increase both the existing smelter capacity of 58,000 tons and the refinery capacity of 39,000 tons to 73,000 tons by the end of 1978 which will be needed to take care of the expansion of the Cobriza mine and increases in purchased concentrates.

Empresa Minera del Perú (Minero Perú), the State mineral development agency, plans for a first-stage capacity of 36,000 tons per year of copper production from the Cerro Verde oxide copper deposit in southern Peru by use of heap-leaching methods. The underlying Santa Rosa sulfide ores are scheduled for initial mining in 1978 at an annual rate of about 120,000 tons of copper. Other mine developments scheduled for 1978 are the Tintaya deposit estimated to produce 70,000 tons of copper per year, the Ferrobamba/Chalcobamba property at 40,000 tons, the Berenguela property at 20,000 tons, and the Toro Mocho property at 90,000 tons. The following year it is planned to bring into production the Antamina property at 24,000 tons, Michiquillay at 80,000 tons, and Quellaveco at 100,000 tons. Minero Perú has a copper refinery under construction at the port town of Ilo in southern Peru. Initial capacity of 165,000 tons per year is scheduled for November 1975 and continuation of construction is planned to expand capacity to 330,000 tons over the following 3 years.

Southern Peru Copper Corp. (SPCC) operated the Toquepala open pit copper mine and the Ilo copper smelter with production of 134,400 tons of recoverable refined copper. Output was again curtailed by strikes with 49 days lost at the mine and 50 days lost at the smelter. A higher than average ore grade of 1.24% copper helped to mitigate the effects of the strikes on mine production.

Progress on SPCC's Cuajone project in 1974 included driving 4.3 miles of railroad tunnel to bring the total to 14.3 miles of the 17 miles required. Considerable progress was also made on the concentrator, housing, smelter, and powerplant expansion. Cuajone with a design capacity of 170,000 tons of blister copper is scheduled for completion in late 1976. Estimated cost of the project has increased since its start and at the end of 1974 was estimated to cost $620 million, including $70 million during construction.

Compañía Minera del Madrigal, a subsidiary of Homestake Mining Co., processed 197,000 tons of ore at its Madrigal copper-lead-zinc mine in southern Peru and shipped approximately 10,700 tons of copper concentrates to Japan. Ore grade averaged 1.8% copper, 2.8% lead, and 3.0% zinc. Operations remained below design capacity, largely because of unavailability and slow delivery of required equipment and supplies.

Philippines.—Continuing its development into a major world copper producer, the Philippines had 8 major porphyry copper mines producing 138,000 tons of ore daily, 8 other deposits expected to be in production within 3 years, and 18 additional major and promising prospects in the exploration stage. Total reserves of porphyry copper ore in the country were estimated at about 2.7 billion tons grading between 0.30% and 0.64% copper. Economic strains on the industry at yearend created by low copper prices and Japanese requests to cutback on copper shipments were balanced in part by the Philippine Government's decision to reduce the export tax on copper from 6% to 2%. Production by 14 mining companies was 248,600 tons of copper in concentrates and direct shipping grade ore, compared with 243,800 tons the previous year.

Atlas Consolidated Mining & Development Corp., one of the largest copper producers in Asia, increased production of copper contained in concentrates by nearly 7% in 1974 to 96,285 tons. The company operated the Frank open pit, the Lutopan underground mine and a 37,000-ton-per-day mill at the Lutopan ore deposit, and the Biga open pit and a 33,000-ton-per-day mill at the Biga deposit, both on Cebu Island, Central Philippines. Feasibility studies were completed and plans were announced to develop the new Carmen open pit located between the Frank and Biga pits and an associated 35,000-ton-per-day mill with production scheduled to start in late 1976. The Carmen ore body contains reported reserves of 294 million tons grading 0.44% copper. These reserves are in addition to the 769 million tons of 0.47% copper contained in the two operating properties. Atlas also announced plans to construct a new smelter, refinery, and acid plant complex by 1978. Capacity of the smelter will be 130,000 tons of copper.

Marcopper Mining Corp., a subsidiary of Placer Development Ltd., mined a high-grade (0.82%) copper ore zone during the year at its Santa Cruz, Marinduque operation and despite a 13% decrease in the ore milled to 6.45 million tons, production of copper in concentrate increased 13% to 51,670 tons. A total of 181,410 tons of concentrate was produced with a metal recovery of 88.5%. In addition 6,200 tons of leach concentrate was produced. A re-evaluation of ore reserves in 1974 downgraded estimated minable reserves at yearend to 102 million tons a 0.40% cutoff and a 0.58% average grade of copper.

Marinduque Mining and Industrial Corp. operated the Sipalay open pit in Negros Oriental and the Bagacay pit in Samar. At Sipalay completed expansion projects helped increase production for the year to 26,782 tons of contained copper with remaining reserves estimated at 377 million tons of 0.52% copper. Production at Bagacay amounted to 7,692 tons of contained copper with available reserves reported at 2.9 million tons of 1.56% milling grade copper ore and 214,000 tons of 12.72% shipping grade copper ore. An agreement in principle was reached in late 1974 between Marinduque, Lepanto Consolidated Mining Co., and a consortium of small copper producers to build a new copper smelter and refinery near Manila. Tentative plans call for a two-stage project with initial capacity at 88,000 tons per year of refined copper increasing later to 132,000 tons per year. The two major companies will provide financing with help from the Philippine Government.

Philex Mining Corp. increased production in 1974 to 28,894 tons of copper contained in concentrates. The company operated the Santo Tomas underground mine near Benguet, northern Luzon, with reserves of 133 million tons of ore grading 0.47% copper. Plans were announced to expand caving operations and increase mill capacity from 21,000 to 24,000 tons of ore per day by 1977.

Lepanto Consolidated Mining Co. operated one of the few nonporphyry copper mines in the country, a massive stratabound-volcanic underground ore deposit located in Mt. Province, northern Luzon. The decrease in production to 15,942 tons of copper contained in concentrates was directly related to difficulties in marketing concentrates with a high arsenic content. ASARCO, who normally handles the bulk of Lepanto concentrates had delayed a decision on a long-term smelting contract with Lepanto pending the impact of U.S. arsenic air pollution regulations on the future of its Tacoma, Wash., smelter. Reserves at the Lepanto mine were estimated at the beginning of the year at 9.4 million tons of 2.77% copper and 0.123 ounce of gold per ton. Lepanto also continued work on development of its Hinobaan deposit in Negros Occidental. Plans called for a $68 million investment to install a 20,000-ton-of-ore-per-day mine and mill operation to exploit reported reserves of 108 million tons of 0.5% copper.

Two new copper producers came on full stream during 1974, Apex Exploration and Mining Co., Inc., and Western Minolco Corp. Apex which began operation of the Masara project in Davao del Norte, Mindanao, in September 1973 produced 629 tons of contained copper in 1974. The Masara project includes mining of the new Kurayao and Wagasara open pits, the construction of a leach plant to reclaim the 2,300 tons of recoverable copper contained in the Sorina dump of the old Hope mine, the rehabilitation of the Masara mine workings, and the setting up of a 10,000-ton-of-ore-per-day mill at Wagas-Mapula. Reserves in the Kurayao area were reported at 4 million tons of 0.42% copper and at Wagas-Mapula at 31 million tons of 0.41% copper. Western Minolco began mining operation at its Boneng and Lobo ore bodies in Benguet, northern Luzon, in February 1974. Production of 21,920 tons of concentrates in 1974 contained 5,929 tons of copper. Plans were also announced to increase the initial mill capacity of 15,000 tons of ore per day to 30,000 tons of ore per day, equivalent to about 50,000 tons of contained copper annually by 1976. Combined ore reserves at Boneng-Lobo are estimated at 108 million tons of 0.48% copper.

Poland.—In 1974 production of copper increased 23% to 209,400 tons. Poland eventually plans to become one of the world's major copper exporters with annual production of around 400,000 tons. This program will require investments estimated at $1 billion with a substantial share expected to be obtained from interests in the United States.

Rhodesia, Southern.—M.T.D. (Mangula) Ltd. during the year ending September 30, 1974, produced 16,800 tons of copper in concentrate and precipitates from the Mangula mine about 80 miles northwest of Salisbury. Concentrates containing 14,600 tons of copper were produced from milling 1.4 million tons of sulfide ore and precipitates containing 1,200 tons of copper were produced from treating 270,000 tons of an oxidized ore in the leach plant. Leach plant operations were closed between December 1973 and July 1974 due to a shortage of sulfuric acid. Proven sulfide ore reserves were 16.5 million tons averaging 1.25% copper and oxidized ore reserves amounted to 0.5 million tons of 0.83% oxide copper. The Norah and Silverside mines produced 3,200 and 1,800 tons of copper in concentrates, respectively. Proven sulfide ore reserves were 2.1 million tons of 1.36% copper at the Norah mine and 640,000 tons of 1.75% copper at the Silverside mine.

Lomagundi Smelting and Mining Ltd. produced 2,300 tons of copper in concentrate from mining and milling 340,000 tons of ore from the Alaska mine. The Shackleton mine yielded 10,160 tons of copper in concentrate from 670,000 tons of 1.85% copper ore. Proved reserves at yearend were 1.0 million tons of 1.19% copper at the Alaska mine and 1.7 million tons of 2.14% copper at the Shackleton mine. The Gwai River mine produced 1,400 tons of copper in concentrate from mining and milling 195,000 tons of 0.79% copper ore. Proved ore reserves were 240,000 tons of 1.00% copper.

South Africa, Republic of.—O'okiep Copper Co. Ltd. mined and milled 3.2 million tons of ore with an average grade of 1.28% copper which yielded 35,800 tons of blister copper compared with 37,800 tons in 1973. Ore reserves at O'okiep mines at the end of 1974 were estimated at 29.1 million tons averaging 1.65% copper. Adverse market conditions in the latter half of the year caused suspension of development at the Spektakel and Divide nonproducing mines and development of deep ore zones at the Carolusberg mine. Also production from mines with low-grade ore was curtailed. O'okiep and the Tsumeb Corp. Ltd. (South-West Africa) began engineering work on a new 130,000-ton-per-year electrolytic copper refinery in the Capetown area to refine the smelter output of the two companies. However, the project has been deferred pending improvment of economic conditions.

Palabora Mining Co. Ltd. had a smelter production of 101,900 tons of copper, a 4% decline from 1973. Ore milled was 21.2 million tons of 0.56% copper compared with 21.2 million tons of 0.57% copper in 1973. A planned major expansion of the open pit mining and ore processing facilities was announced with completion expected early in 1977. Milling capacity will be increased from an average 58,000 to 82,000 tons of ore per day, equivalent to 138,000 tons of copper annually. The capacity of the electrolytic refinery will be increased to handle the entire copper output.

Messina (Transvaal) Development Co. mined and milled 1.2 million tons of 1.04% copper ore from its Messina mine which yielded 11,300 tons of copper in concentrate. The tonnage of proved ore reserves at yearend was estimated at 5.7 million tons averaging 1.45% copper.

Phelps Dodge Corp. carried out pilot plant testing of bulk ore samples from the most promising of two copper-lead-zinc-silver discoveries in the vicinity of Aggeneys in Cape Province. Proven reserves in the open pit portion of this ore body were estimated at 79 million tons averaging 0.38% copper, 4.28% lead, 2.32% zinc, and 1.7

ounces of silver per ton. Arrangements were in progress to obtain power and water for planned mining operations.

South-West Africa, Territory of.—The Tsumeb Corp. Ltd. mined 464,000 tons of ore from the Tsumeb mine averaging 4.36% copper, 10.06% lead, and 2.30% zinc. At the Kombat mine 389,000 tons of ore grading 1.19% copper and 2.62% lead was mined. The Matchless mine, near Windhoek, reopened in 1973, produced 119,000 tons of ore averaging 1.93% copper in 1974. Smelter production at Tsumeb was 51,400 tons of blister compared with 39,700 tons in 1973. The smelter is being expanded to an annual capacity of 79,000 tons which will enable custom smelting of concentrates from other mines in South-West Africa. Ore reserves as of the end of 1974 were estimated at 6.1 million tons assaying 4.56% copper, 7.79% lead, and 2.06% zinc for the Tsumeb mine; 1.2 million tons of 1.91% copper and 3.32% lead for the Kombat mine; and 1.3 million tons of 2.28% copper at the Matchless mine.

Oamites Mining Co. (Pty.) Ltd. (75% Falconbridge) milled 680,000 tons of ore grading 1.13% copper. Metal recovery in 21,000 tons of concentrate was 91.32% yielding 7,000 pounds of copper. Ore grade was down from 1.35% in 1973 due to decreasing and proportionately diluted vein width towards the limits of the ore body.

Spain.—Rio Tinto-Patiño, S.A. (RTP), operated the Cerro Colorado open pit mine and a custom smelter and refinery in the southern province of Huelva in 1974. RTP treated over 3 million tons of copper ore, a decrease of 8% from 1973. Copper output was 23,900 tons. Ore reserves include 61 million tons of 0.71% copper at Cerro Colorado and 20 million tons of 0.69% copper at Santiago. The Santiago open pit copper deposit in the northwestern province of Galicia is scheduled to start operations in the second quarter of 1975 at a mining rate of 4,400 tons daily. The RTP smelter produced 52,800 tons of anode copper from primary concentrate and cement copper feed and 49,900 tons from secondary sources. Planned startup of a new flash smelter and a second acid plant in 1975 will double the rated smelter capacity to 93,000 tons of copper. The electrolytic refinery which produced 80,800 tons of cathode copper for the year is scheduled to expand its capacity to 116,000 tons in 1975.

Uganda.—Kilembe Mines Ltd. (73% Falconbridge) reportedly encountered difficulty in maintaining operations on an economic basis during the year due to a combination of local supply shortages, lack of trained personnel, difficulties in moving imported goods from port to the mine, and lower copper prices. Negotiations with the Uganda Government were in progress to attempt to resolve the difficulties. Production of milled ore decreased 14% to 780,200 tons and blister copper 8% to 9,800 tons.

Yugoslavia.—Estimated primary production of copper by Rudarsko Topionicarski Bazen (RTB), Bor, Serbia, in 1974 included 136,000 tons of copper in concentrate, 180,000 tons of blister copper and 154,000 tons of refined copper. In addition to domestic material the smelter handled 38,600 tons of imported ore and concentrates, chiefly from Chile. RTB operated a mine, flotation plant, and smelter at Bor, and a mine and flotation plant at Majdanpek. Development work continued on a large deposit of low-grade ore at Krivelj with plans for an annual capacity of 66,000 tons of copper to be reached by 1981. Work also continued on the development of the second major copper-producing facility in Yugoslavia at Bucim, near Radoviste, Macedonia. Work on a mine and beneficiation plant at the Bucim copper deposit were started during the year with a two-phase project scheduled to reach an annual capacity of 23,000 tons of copper by 1977 with a later expansion to 66,000 tons.

Zaire.—In major actions affecting copper production the Government of Zaire announced its firm determination to have the country's entire copper production refined domestically by 1980. By that year expansions announced under the Second 5-Year Plan combined with the two private/Government joint venture developments currently underway are scheduled to increase Zaire's annual copper production to 880,000 tons. The Government also reached an agreement in principle to compensate the Belgian company. Union Minière du Haut Katanga, with a sum of $100 million for the 1967 expropriation of its mines now run by the State agency La Générale des Carrières et Mines du Zaire (Gécamines).

Copper production in Zaire increased

2% to 549,900 tons. Gécamines which operates 10 mines, 5 mills, 2 copper smelters at Lubumbashi and Panda and 2 copper-cobalt refineries at Shituru and Luilu in Shaba Province produced 519,100 tons of copper including 357,000 tons of copper in refined shapes. Plans to increase annual production of copper to 628,000 tons by 1978 include the development of two new open pit mines, Dikuluwe and Mashambe, a new mill with an annual capacity of 4 million tons of ore, a flash smelter and an electrolytic refinery all near Kolwezi, Shaba. The two new mines with combined reserves estimated at 171 million tons of 4.1% copper and 0.3% cobalt are due to open in late 1975.

The joint Zairian Government-private Japanese concern, Société de Dévelopment Industriel et Minière du Zaire (SODIMIZA), in its second full year of operating the Mushoshi mine and mill in Shaba Province increased mine production 10% to 1.5 million tons of ore in 1974. Production of 85,000 tons of concentrate with an average copper content of 36% yielded 30,500 tons of contained copper. SODIMIZA continued development of the Kinsenda mine during the year seeking the most suitable mine design to exploit an irregular-shaped ore body and to control serious ground water problems. Production is not expected to begin before 1977 or 1978. Previous estimates placed ore reserves at Mushoshi at 110 million tons of 3.5% copper with 35 million tons of 5.5% copper at Kinsenda.

Société Minière de Tenke-Fungurume (SMTF), a consortium of American, British, French, and Japanese companies and the Government of Zaire, continued construction and development of the Tenke-Fungurume project during the year. The scheduled startup date for the planned 165,000-ton-capacity refinery may be delayed past 1977 pending the completion of installation of the new Inga Dam to Shaba electric power transmission lines. Inflation has raised the cost of the SMTF project to over $700 million. Reserves of mixed oxide and sulfide ore were estimated at 52 million tons of 5.4% copper and 0.42% cobalt. SMTF plans to use a process involving the conversion of sulfides to oxides prior to recovery of copper by leaching, solvent extraction, and electrowinning.

Zambia.—Transport problems resulting from the 1973 border closure with Southern Rhodesia continued and the alternate road routes to Dar es Salaam, Tanzania, and Mombasa, Kenya, and the rail route to Lobito, Angola, were utilized for shipment of copper. Completion of the Tanzania-Zambia Railway (Tazara), scheduled for mid-1975, will improve transportation although congestion at the terminal port of Dar es Salaam could continue to be a problem.

Roan Consolidated Mines, Ltd. (RCM), operated the Mufulira, Chibuluma, Chambishi, Kalengwa, and Luanshya mines that produced 321,000 tons of copper for the year ended June 30, 1974, compared with 305,000 tons in 1973. Increased recovery at the Mufulira mine reflected continued recovery from the 1970 cave-in and flooding accident. At Luanshya there was greater output from the Baluba section and at Chambishi both ore mined and the copper grade increased. Production from Chibuluma was adversely affected by a decline in grade of ore mined.

Development of Kalulushi East, south of Chibuluma, continued. Ore reserves were estimated at 4.2 million tons averaging 4.15% copper. Initial production is scheduled for 1979 and will attain full production in 1981 to compensate for the phasing out of ore supply from the two shafts at Chibuluma during the same time.

Nchanga Consolidated Copper Mines Ltd. (NCCM), through the Rokana, Chingola, and Konkola Divisions, operated copper mines, a smelter, and a refinery. Mine production was 451,000 tons of copper for the year ended March 31, 1974, compared with 485,000 tons for the preceding year. The decline in output was largely associated with disruptions caused by an expansion program designed to achieve an annual rate of 550,000 tons by mid-1975. At the Konkola concentrator the high-grade leach plant produced a record 123,000 tons of copper, but delays due to shortage of construction materials affected production at the low-grade leach plant. Initial output of the solvent extraction-ion exchange process plant began in December 1973 and was fully operational in mid-1974. A decision was made to proceed with reopening of the Kasanshi mine located near Solwezi in the Northwestern Province that was closed by flooding in 1957. Operations will consist of an open pit mine and a leach-solvent extraction-electrowinning plant with a rated annual capacity of 28,000 tons of copper. Initial production is scheduled for late 1977.

Geomin, a Romanian-based mineral development company, in a joint venture with Mindeco Ltd., formed a new company, Mikambo Development Co., Ltd., to investigate the feasibility of beginning operations at Mikambo, near the Zairian border. The mine is believed to contain sufficient reserves to produce 16,000 tons of copper in concentrate annually for about 12 years.

TECHNOLOGY

Results of research[3] on mineralization relationships for seven low-grade and subeconomic porphyry copper deposits in western Canada may be usefully applied to the search for additional deposits. Findings included identification of normal outward zoning patterns from biotite-chalcopyrite to chlorite-carbonate-pyrite. Deep brown, coarse-grained, sugary-textured hydrothermal biotites are associated with relatively strong copper mineralization, whereas greenish and/or fine grained hydrothermal biotites are indicative of weak copper mineralization.

An open pit model and two underground models were developed to generate information on various aspects of mining the copper-nickel resources associated with the Duluth Gabbro Complex in northeastern Minnesota.[4]

To better understand those factors which increase mining costs in Alaska, a study was conducted to compare the estimated costs of producing copper from similar hypothetical porphyry deposits in Alaska and Arizona.[5] An evaluation of truck haulage costs included factors of capital costs, operating costs, reliability of operation, and indirect costs.[6]

A metal detection device using high-frequency alternating current was used in tests to determine applicability in upgrading native copper ores.[7] Research on recovering copper from mill tailings at 11 operations indicated recoveries from 15% to 65% with concentrate grades from 2% to 13% copper.[8] A report[9] summarizes procedures and costs for stabilizing mill tailings by chemical, vegetative, and combination procedures.

Several publications[10] described research conducted on recovering copper from chalcopyrite by application of hydrometallurgical methods. Results of batch tests on the cementation of copper on iron at elevated temperatures showed sufficient promise to justify development of a continuous-flow copper recovery process.[11] The continuous-flow tests produced copper in powder form exceeding 99.8% purity with a reaction rate more than 100 times that of conventional launder systems and with about a 0.9 ratio of iron consumption to copper production.

Experiments conducted to identify controlling parameters in loss of copper in smelter slags concluded that reduction of sulfur solubility by means of slag composition was a key factor.[12] Full-scale autogenous smelting tests on copper concentrate using a top-blown rotary converter (TBRC) successfully demonstrated the applicability of this process to produce blister copper.[13] Advantages of the TBRC process include relatively low capital and maintenance costs, low overall energy requirements, and up to 50% SO_2 concentrations in exhaust gases, facilitating economic recovery of sulfur.

Problems associated with alternative solutions to implement regulations for control of sulfur emissions at copper smelters are discussed in an article.[14] Another publication [15] estimated the comparative costs of five smelting procedures with SO_2 removal from stack gases ranging from 0% to 99%. Research developed a pyrometallurgical process to recover 98% of the zinc and 12% to 25% of the lead from brass smelter dusts.[16]

Laboratory investigations indicated that X-ray methods are capable of separating standard copper-base alloys into 10 general classes. These methods have a possible application for scrap metal recovery systems.[17]

Research using electron diffraction pattern techniques investigated changes in the crystal lattice pattern during aging for certain copper-titanium alloys.[18]

Table 7.—Mine production of recoverable copper in 1974, by method of treatment

Method of treatment	Ore treated (thousand short tons)	Recoverable copper: Thousand pounds	Recoverable copper: Percent yield	Remarks
Copper ore:				
By concentration	269,016	2,692,182	0.50	See table 9.
By smelting	305	7,700	1.26	See table 10.
By leaching	24,122	[1] 153,051	.32	See table 11.
Total	293,443	2,852,933	.49	
Dump and in-place leaching	--	292,215	--	See table 11.
Miscellaneous from cleanup, tailings, and noncopper ores	--	48,856	--	--
Total	XX	3,194,004	XX	--

XX Not applicable.

[1] Includes 59,986,983 pounds of electrowon copper.

Table 8.—Copper ore shipped directly to smelters or concentrated in the United States, by State in 1974, with copper, gold, and silver content in terms of recoverable metal

State	Ore shipped or concentrated (thousand short tons)	Recoverable metal content: Copper: Thousand pounds	Recoverable metal content: Copper: Percent	Recoverable metal content: Gold (troy ounces)	Recoverable metal content: Silver (troy ounces)	Value gold and silver per ton of ore
Arizona	161,221	1,490,740	0.46	89,765	6,266,783	$0.27
Colorado	11	397	1.81	339	115,404	54.46
Idaho	86	963	.56	82	22,162	1.36
Michigan	8,301	134,024	.81	--	642,944	.36
Montana	23,142	224,616	.49	24,308	3,249,733	.83
Nevada	13,467	113,947	.42	31,643	401,127	.52
New Mexico	26,343	342,043	.65	14,469	1,040,205	.27
Tennessee [1]	1,153	12,607	.55	18	20,053	.08
Utah	35,443	376,061	.53	250,235	2,325,360	1.44
Other States	154	4,484	1.45	7	23,050	.71
Total	269,321	2,699,882	.50	410,866	14,106,821	.49

[1] Copper-zinc ore.

Table 9.—Copper ore concentrated [1] in the United States, by State in 1974, with content in terms of recoverable copper

State	Ore concentrated (thousand short tons)	Recoverable copper content: Thousand pounds	Recoverable copper content: Percent
Arizona	160,981	1,483,449	0.46
Colorado	6	125	.99
Idaho	86	963	.56
Michigan	8,301	134,024	.81
Montana	23,140	224,584	.49
Nevada	13,467	113,947	.42
New Mexico	26,285	341,965	.65
Tennessee [2]	1,153	12,607	.55
Utah	35,443	376,061	.53
Other States	154	4,457	1.45
Total	269,016	2,692,182	.50

[1] Includes following methods of concentration: "Dual process" (leaching followed by by concentration); "LPF" (leach-precipitation-flotation); and froth flotation.

[2] Copper-zinc ore.

Table 10.—Copper ore shipped directly to smelters [1] in the United States, by State in 1974, with content in terms of recoverable copper

State	Ore shipped to smelters		
	Short tons	Recoverable copper content	
		Pounds	Percent
Arizona	239,895	7,290,732	1.52
Colorado	4,669	272,447	2.92
Montana	1,744	31,829	.91
Nevada	57	111	.10
New Mexico	58,243	78,362	.07
Other States	64	26,373	20.60
Total	304,672	7,699,854	1.26

[1] Primarily smelter fluxing material.

Table 11.—Copper precipitates (from dump or in-place leaching) shipped directly to smelters and copper ore leached (heap, vat, or tank) in the United States, by State in 1974, with content in terms of recoverable copper

State	Precipitates shipped (short tons)	Recoverable copper content (pounds)	Ore leached (short tons)	Recoverable copper content (pounds)	Percent
Arizona	74,590	107,385,137	[1] 17,599,767	[2] 112,619,172	0.63
Montana	23,695	37,347,091	--	--	--
Nevada	13,653	19,140,385	6,481,914	34,544,027	.27
New Mexico	31,891	50,007,745	--	--	--
Utah	48,661	78,244,604	39,920	5,887,796	7.37
Other States	68	89,918	--	--	--
Total	192,558	292,214,880	24,121,601	153,050,995	.32

[1] Includes 8,712,485 short tons of ore leached for electrowinning.
[2] Includes 59,986,983 pounds of electrowon copper.

Table 12.—Copper ore smelted and copper ore concentrated in the United States, and average yield in copper, gold, and silver

Year	Smelting ore		Concentrating ore		Total				
	Thousand short tons	Yield in copper, percent	Thousand short tons [1] [2]	Yield in copper, percent	Thousand short tons [1]	Yield in copper, percent	Yield per ton in gold, ounce	Yield per ton in silver, ounce	Value per ton in gold and silver
1970	542	3.51	235,586	0.60	257,729	0.59	0.0023	0.067	$0.20
1971	453	1.76	222,121	.56	242,656	.55	.0022	.059	.18
1972	484	1.68	248,663	.55	266,831	.55	.0019	.059	.21
1973	337	1.40	272,688	.53	289,998	.53	.0018	.058	.32
1974	305	1.26	269,016	.50	293,443	.49	.0014	.048	.45

[1] Includes some ore classed as copper-zinc and minor amount of tailings (1971 excludes tailings).
[2] Excludes tank or vat and heap leaching. (See tables 7 and 11).

Table 13.—Copper produced by primary smelters in the United States

(Short tons)

Year	Domestic	Foreign	Secondary	Total
1970	1,605,265	36,073	78,897	1,720,235
1971	1,470,815	29,181	66,333	1,566,329
1972	1,649,130	41,263	69,017	1,759,410
1973	1,705,065	38,898	77,815	1,821,778
1974	1,532,066	37,750	79,543	1,649,359

Table 14.—Primary and secondary copper produced by primary refineries in the United States

(Short tons)

	1970	1971	1972	1973	1974
PRIMARY					
From domestic ores etc.:[1]					
Electrolytic	1,359,751	1,274,084	1,520,943	1,536,819	1,298,712
Lake	66,091	57,218	70,025	78,179	66,624
Casting	95,341	79,221	89,444	83,339	55,569
Total	1,521,183	1,410,523	1,680,412	1,698,337	1,420,905
From foreign ores, etc.:[1]					
Electrolytic	215,088	167,213	160,781	159,786	202,127
Casting and best select	28,823	14,046	32,040	10,365	31,626
Total refinery production of primary copper	1,765,094	1,591,782	1,873,233	1,868,488	1,654,658
SECONDARY					
Electrolytic[2]	433,394	323,913	341,581	377,523	398,976
Casting	17,623	18,599	16,667	14,290	13,543
Total secondary	451,017	342,512	358,248	391,813	412,519
Grand total	2,216,111	1,934,294	2,231,481	2,260,301	2,067,177

[1] The separation of refined copper into metal of domestic and foreign origin is only approximate, as accurate separation is not possible at this stage of processing.

[2] Includes copper reported from foreign scrap.

Table 15.—Copper cast in forms at primary refineries in the United States

	1973		1974	
	Thousand short tons	Percent	Thousand short tons	Percent
Billets	133	6	101	5
Cakes	147	6	132	6
Cathodes	584	26	661	32

Other forms	21	1	13	1
Total	2,260	100	2,067	100

Table 16.—Production, shipments, and stocks of copper sulfate

(Short tons)

Year	Production		Shipments	Stocks Dec. 31[1]
	Quantity	Copper content		
1970	45,352	11,338	40,324	8,812
1971	34,648	8,662	36,852	5,936
1972	38,052	9,513	37,964	5,828
1973	43,360	10,840	44,092	4,580
1974	42,092	10,523	43,598	3,074

[1] Some small quantities are purchased and used by producing companies, so that the figures given do not balance exactly.

Table 17.—Byproduct sulfuric acid[1] (100% basis) produced in the United States

(Short tons)

Year	Copper plants[2]	Lead plants	Zinc plants[3]	Total
1970	747,784	1,090,817		1,838,601
1971	803,284	971,946		1,775,230
1972	1,010,614	859,103		1,869,717
1973	1,088,322	146,591	819,537	2,054,450
1974	1,277,440	132,594	830,969	2,241,003

[1] Includes acid from foreign materials.

[2] Excludes acid made from pyrites concentrates.

[3] Excludes acid made from native sulfur.

Table 18.—Secondary copper produced in the United States

(Short tons)

	1970	1971	1972	1973 r	1974
Copper recovered as unalloyed copper	521,137	429,095	447,409	484,623	513,308
Copper recovered in alloys [1]	726,465	771,025	853,564	892,534	831,012

---

[1] Brass-mill stocks include home scrap; purchased scrap consumption assumed equal to receipts, so lines in brass-mill and grand total sections do not balance.

[2] Of the totals shown, chemical plants reported the following: Unalloyed copper scrap, 1,120 tons new and 2,177 old.

[3] Includes refinery brass.

Table 24.—Consumption of copper and brass materials in the United States by principal consuming groups

(Short tons)

Year and item	Primary producers	Brass mills	Wire mills	Foundries, chemical plants, and miscellaneous users	Secondary smelters	Total
1973:						
Copper scrap	603,830	776,714	--	80,462	402,123	1,863,129
Refined copper[1]	--	714,438	1,672,255	39,760	10,595	2,437,048

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Data presented represent copper content (recoverable where indicated) of ore mined wherever possible. If such data are not available, the nonduplicative total copper content of ores, concentrates, matte, metal and/or other copper-bearing products measured at the least stage of processing for which data are available has been used.

[2] Recoverable.

[3] Copper content of concentrate produced.

[4] Corporación Minera de Bolivia (COMIBOL) production plus exports by medium and small mines.

[5] Smelter production.

[6] Includes copper content of cupriferous pyrites.

[7] Excludes an unreported quantity of copper in iron pyrites which may or may not be recovered.

[8] Year ending September 30 of that stated.

[9] Data are compiled from operating company reports of Tsumeb Corp. Ltd., General Mining and Finance Corp. Ltd. for Klein Aub Koper Maatskappy Ltd.'s mine near Rehoboth, and Falconbridge Nickel Mines Ltd. for Oamites Mining Company (Pty.) Ltd., Oamites mine. Data for General Mining and Finance Corp. Ltd. are for fiscal years ending June 30 of that stated, while data from other companies are for calendar years.

[10] Copper content of matte produced.

[11] Year beginning March 21 of that stated.

[12] Copper content of concentrate. Copper content of run-of-mine production was as follows in short tons: 1972—125,248; 1973—103,871; 1974—90,985.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Unless otherwise noted, data presented for each country represented primary copper metal output, whether produced by thermal or electrowinning. To the extent possible, refined copper produced from imported blister or electrolytic anode copper has been excluded

[2] Copper content of impure bars and electrolytic copper.

[3] Smelter output of domestic and foreign ores, exclusive of that from scrap. Production from domestic ores only was as follows in short tons: 1972—1,649,130; 1973—1,705,065; and 1974—1,532,066.

[4] Figures presented are total blister and equivalent copper output including that blister subsequently refined in Chile and copper which is produced by electrowinning. Material produced for refining at Ventanas smelter is included.

[5] Belgium reports a large output of refined copper, but this is produced mainly from import blister; domestic smelter production is reported output of blister copper from ores.

[6] Reported Norwegian copper output is derived in part from copper-nickel matte imported from Canada, and reported Canadian smelter production may also include this material. Norwegian smelter output from domestic ores was as follows (approximately) in short tons: 1972—7,500; 1973—7,500; and 1974—6,500.

[7] Refined output.

[8] Year ending September 30 of that stated.

[9] Data are compiled from operating company reports of Tsumeb Corp. Ltd., General Mining and Finance Corp. Ltd. for Klein Aub Koper Maatskappy Ltd.'s mine near Rehoboth, and Falconbridge Nickel Mines Ltd. for Oamites Mining Company (Pty.) Ltd., Oamites mine. Data for General Mining and Finance Corp. Ltd. are for fiscal years ending June 30 of that stated, while data from other companies are for calendar years.

[10] Figure comprises reported production of Tsumeb Corp. Ltd. and Oamites Mining Company (Pty.) Ltd. plus an estimate for Klein Aub Koper Maatskappy Ltd.

[11] Data include refined copper plus exported blister and leach cathodes.

[12] Includes secondary.

[13] Year beginning March 21 of that stated.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Unless otherwise noted, data presented for each country represent total primary refined copper (both fire refined and electrolytically refined), including material refined from imported crude copper (blister and electrolytic anode).

[2] Includes secondary.

[3] Includes electrolytic output of the Ventanas refinery.

[4] Data include leach cathodes from Zaire, secondary, and alloy material.

[5] Year ending September 30 of that stated.

[6] Excludes metal content of leach cathodes which are included in Belgium production.

Diatomite

By Stanley K. Haines [1]

Domestic production of diatomite increased in 1974 for the third consecutive year. Diatomite sold or used by producers in the United States increased 9% in quantity and 40% in value compared with that of 1973. The United States remained a major world producer of processed diatomite. U.S. exports of processed diatomite increased in both quantity and value over those of 1973.

DOMESTIC PRODUCTION

All U.S. diatomite production was derived from open pit operations in California, Kansas, Nevada, Oregon, and Washington. California continued as the largest producing State.

During 1974, 11 companies, with a total of 17 mine or plant operations, mined and processed diatomite to supply the demand of various industrial end users. The following companies supplied the bulk of the processed diatomite production: Johns-Manville Products Corp., with a quarry and processing plant near Lompoc, Calif.; Grefco, Inc., with operations near Lompoc, Calif., and Mina, Nev.; Eagle-Picher Industries, Inc., with facilities near Sparks and Lovelock, Nev.; and Kenite Corp., Division of Whitco Chemical Corp., with an operation near Quincy, Wash. The remaining producers were Excel-Minerals Co., near Taft, Calif.; Airox Earth Resources, Inc., near Santa Maria, Calif.; NL Industries, Inc., near Wallace, Kans.; Fernley Division, Cyprus Mines Corp., near Fernley, Nev.; and A. M. Matlock and American Fossil, Inc., both near Christmas Valley, Oreg.

Eagle-Picher Industries, Inc., announced plans for a $5 million expansion of the company's diatomite filter aid facilities at Lovelock, Nev. Production capacity of the plant will be increased about 50% when the project is completed.

Table 1.—Diatomite sold or used by producers in the United States

	1970	1971	1972	1973	1974
Domestic production (sales) ---- short tons ----	597,636	535,318	576,089	608,906	664,303
Average value per ton ----------------------------	$54.63	$64.25	$65.19	$59.26	$76.31

CONSUMPTION AND USES

All major end uses reported gains in quantities consumed. Filtration continued as the major end use of diatomite accounting for three-fifths of domestic demand. Abrasives, industrial filters, and lightweight aggregates accounted for over one-fifth of demand. The remainder was consumed in miscellaneous uses such as pozzolan, inert carrier, and coating agent.

---

[1] Geologist, Division of Nonmetallic Minerals.

Table 2.—Domestic consumption of diatomite, by principal use
(Percent of total consumption)

Use	1970	1971	1972	1973	1974
Filtration	58	59	58	61	60
Fillers	19	W	W	W	W
Insulation	4	3	4	4	5
Miscellaneous	19	38	38	35	35

W Withheld to avoid disclosing individual company confidential data; included with "Miscellaneous."

PRICES

The weighted average value per ton of diatomite, for all end uses in 1974, increased almost 29% over that of 1973. The increases were caused by a combination of general inflation and the higher cost for energy needed in processing the diatomite. Prices of diatomite used in filtration and as fillers increased 34% and 24%, respectively.

Table 3.—Average annual value per ton of diatomite, by use

Use	1973	1974
Filtration	$65.18	$87.40
Insulation	50.39	55.59
Abrasives	125.46	129.51
Fillers	62.01	77.12
Lightweight aggregate	45.02	47.31
Miscellaneous	36.99	46.25
Weighted average	59.26	76.31

FOREIGN TRADE

Exports of prepared diatomite increased 4% in quantity and 21% in value over those of 1973. Exports represented 28% of domestic production. Major countries of destination were Canada, 41,857 short tons; Japan, 19,896 tons; the United Kingdom, 16,667 tons; the Federal Republic of Germany, 14,587 tons; Australia, 12,585 tons; and the Republic of South Africa, 8,637 tons. The remainder was shipped to many other countries for various end uses. The average value of exported material was $94.31, and represented a 16% increase over that of 1973. Imports of diatomite totaled 3,690 tons, valued at $264,438. The primary source of imports was Mexico, minor quantities were received from Kenya and the United Kingdom.

Table 4.—U.S. exports of diatomite
(Thousand short tons and thousand dollars)

Year	Quantity	Value
1972	148	12,603
1973	178	14,582
1974	186	17,541

WORLD REVIEW

Preliminary 1974 data indicate an increase in production of over 86,000 short tons, a 5% increase over 1973 production. The United States continued to lead all other nations in production of diatomite.

Feldspar, Nepheline Syenite, and Aplite

By J. Robert Wells [1]

Feldspar production, processing, and utilization all scored advances in 1974, more than compensating for such negative factors as fading fuel supplies, multiplying health and safety regulations, and indirectly the high price of sugar.

Expenditures for more and more costly oil and natural gas (used by most major producers for drying flotation-cake feldspar) continued to mount in coincidence with the necessity for unprecedented outlays for labor, operating supplies, and all mining and processing equipment, whether new items or spare parts and replacements.

In common with most other mineral production and processing activities, the feldspar industry is subject to rules governing land use, mined-area reclamation, working conditions, and control of air and water pollution that are issued by the Federal Government, including the Environmental Protection Agency (EPA), the Interior Department's Mining Enforcement and Safety Administration (MESA), and the Labor Department's Occupational Safety and Health Administration (OSHA), as well as by some State and local authorities. It was reported that in 1974 substantial and increasing portions of the feldspar industry's operating funds and technical capabilities were being diverted from direct production-oriented considerations toward efforts to comply with those demands.[2] In early 1974, inadequate observation of industrial hygiene precautions led to a MESA ruling that temporarily suspended production of high-potash feldspar in South Dakota.

The relationship of high sugar prices to feldspar may not have been as direct or as easy to trace as that of government controls, but its effects were no less striking. Soaring sugar prices increased the cost of sugar-heavy bottled drinks and also induced a less explicable boost in the price of "sugar-free" dietetic varieties. These increases, coupled with rising prices for staple food items, made it relatively easy for the shopper to defer beverage purchases, thereby notably depressing soft drink sales in the last half of 1974.[3]

The manufacture of disposable beverage bottles, the next negative factor in line, had been outstandingly prosperous, with uninterrupted, conspicuous annual increases for as long as separate statistics have been published (since 1960), but the 1974 output of those convenient containers departed sharply from the trend and fell 4.4 million gross (or 7%) below the 1973 figure.[4] The makers of glass containers have been the foremost consumers of feldspar and related substances for many years, and the feldspar industry may well feel at least a few ripples in 1975 from the wave of shoppers bypassing the soft drink shelf in 1974.

Legislation and Government Programs.—According to provisions of the Tax Reform Act of 1969, which continued in force throughout 1974, the depletion rates allowed on feldspar production (both domestic and foreign operations) was 14%.

FELDSPAR

DOMESTIC PRODUCTION

Unground Feldspar.—The 1974 output of feldspar ready to be put into final form for use was 8% more in quantity and 13% more in total value than in 1973. This output comprises hand-cobbed feldspar, flotation-concentrate feldspar, and the feldspar content of feldspar-silica mixtures, for which the collective term "unground feldspar" is perhaps somewhat less ambiguous than the former designation "crude feldspar."

Feldspar was mined in 1974 in nine States (one more than in 1973), among which North Carolina, Connecticut, Georgia, California, and South Dakota jointly supplied 98% of the national total; Arizona, Colorado, Oklahoma, and Wyoming made up the remainder.

There were a number of events in 1974 that affected the pattern of feldspar production in the United States. Sobin Chemicals, Inc., acquired International Minerals & Chemical Corp.'s feldspar producing and processing facilities near Spruce Pine, N.C., and continued to operate them under the name of Ceramics and Glass Products Division of Sobin Chemicals. Lithium Corporation of America, a subsidiary of Gulf Resources and Chemical Corp., secured title to the stock and properties of Spartan Minerals Co. at Pacolet, S.C. The newly formed Spartan Minerals Division of Lithium Corporation, will continue operation of the Pacolet plant, producing feldspar and other minerals from pegmatite ores that will be mined in North Carolina.

In that same region, Foote Mineral Co. announced the forthcoming construction of a large new facility at Kings Mountain, N.C., to produce lithium carbonate from spodumene extracted from pegmatites. Recovery of accessory minerals from Kings Mountain lithium ores has made Foote Mineral an important producer of feldspar.

In the roster of California feldspar producers, the late 1973 closing of Wedron Silica Co.'s Pacific Grove mine in Monterey County was balanced in June 1974 by the inauguration of the California Non-Metallic, Inc., mine and grinding plant at Santa Fe Springs to process feldspar from a deposit at Ord Mountain in San Bernardino County.

[1] Feldspar content.
[2] Data may not add to totals shown because of independent rounding.

Ground Feldspar.—Most of the feldspar used in glassmaking is ground no finer than 20 mesh, and substantial tonnages of feldspathic sands (feldspar-silica mixtures) enter into glass furnace feeds with no further reduction in particle size. Feldspar to be used in ceramics and filler applications is usually pulverized to minus 200 mesh or finer. Nine companies, operating 15 plants in 9 States, ground feldspar for market in 1974, supplying ground material (total tonnage 4% more than 1973) for shipment to destinations in about 25 States, Puerto Rico, Canada, and Mexico. Listed in descending order of output tonnages, North Carolina had six grinding mills, and Connecticut, Georgia, and South Carolina had one each. These were the leaders in ground feldspar production and jointly accounted for 92% of the 1974 total. South Dakota with two mills, followed by Arizona, California, Colorado, and Wyoming with one each, were the five States making up the remaining 8%. Oklahoma was the only feldspar-producing State in 1974 in which no grinding mill was in operation.

CONSUMPTION AND USES

Unground Feldspar.—In 1974 there was, as usual, no significant consumption of feldspar in the raw, unprocessed state in which it is taken from the mine; the majority of users acquired their supplies already ground and sized either by the primary producers or by merchant grinders. Some manufacturers of pottery, soaps, and enamels, however, continued their customary practice of purchasing crude feldspar for grinding to their preferred specifications in their own mills. The Bureau of Mines canvass of producers and merchant grinders does not provide information concerning the end-use distribution of the material handled in this way. It should be noted that a substantial portion of the material classified as feldspar-silica mixtures serves in glassmaking without the need for additional processing, so that this utilization might properly be considered as consumption of unground feldspar.

Ground Feldspar.—The 1974 distribution pattern for ground feldspar indicated in table 3 differs notably from that of 1973 especially in the figures reported for feldspar-silica mixtures. It is thought that the quantities shown in some previous years as being consumed for glass and pottery may have been reported in error because of a misunderstanding about the nature of the material properly classified as feldspar-silica mixtures. The intention has been to apply that term only to material consisting of feldspar and free quartz in approximately equal proportions. Most of the material falling into this category is either feldspathic sand or else a flotation product, neither of which usually requires any further grinding for the end uses they serve.

Table 3.—Ground feldspar sold by merchant mills, by use

Use	1973 Quantity (short tons)	1973 Value (thousands)	1974 Quantity (short tons)	1974 Value (thousands)

STOCKS

From a comparison of 1974 data on domestic production and sales of feldspar, it was estimated that U.S. producers had 251,000 tons of feldspar (unground, ground, or in process) on hand on December 31, 1974.

PRICES

Engineering and Mining Journal, October through December 1974, listed the following prices for feldspar, per short ton, f.o.b. mine or mill, carload lots, bulk, depending on grade (generally $1 to $7.50 per ton higher than the respective quotations of the previous year):

North Carolina:	
20 mesh, flotation	$14.50–$15.50
40 mesh, flotation	14.00– 22.00
200 mesh, flotation	25.50– 29.00
Georgia:	
40 mesh, granular	26.00
200 mesh	31.00
Connecticut:	
20 mesh, granular	19.00
200 mesh	26.00

Feldspar prices were quoted by Industrial Minerals (London), December 1974, as follows (converted from pounds sterling per long ton to dollars per short ton):

Ceramic grade, powder, 200 mesh, bagged, ex-store	$80–$91
Sand, 2–3 millimeters, ceramic/glass grade c.i.f. main European port	31–40

FOREIGN TRADE

In 1974, U.S. exports classified as feldspar, leucite, nepheline, and nepheline syenite (but presumably all or mostly feldspar) amounted to 18,319 tons valued at $661,831, almost double the tonnage reported in 1973 and just under 1½ times the value. Chief recipients of the exported material were Canada, 84%; and Mexico, 13%; the remaining 3% was shared among nine other countries.

In marked contrast to rising exports of feldspar, U.S. imports of the mineral continued along the downward trend of recent years and amounted to only 0.5% of the tonnage exported, and 0.6% of the corresponding value. In addition to feldspar (table 4) and nepheline syenite (table 6), U.S. imports in 1974 included 2,931 tons of material, probably feldspathic in nature, that was classified as "Natural mineral fluxes, crude, crushed, ground, or pulverized" and had a total value of $262,145.

The tariff schedule in force throughout 1974 provided for a 3½% ad valorem duty on ground feldspar; imports of unground feldspar were admitted duty free.

Table 4.—U.S. imports for consumption of feldspar

Country	1973 Quantity (short tons)	1973 Value	1974 Quantity (short tons)	1974 Value
Unground:				
Canada	46	$3,725	30	$617
South Africa, Republic of	218	17,870	--	--
Total	264	21,595	30	617
Ground, crushed or pulverized:				
Canada	103	3,549	23	915

Total	103	3,549	62	3,448

WORLD REVIEW

Canada.—Although the last feldspar mine in Canada (at Buckingham, Quebec) was closed down in 1972, two different organizations have continued exploring the possibility of producing feldspar in another Province. Centex, an association of industry, government, and university groups in Manitoba, had undertaken an assessment of the economics of recovering feldspar and other coproducts from tailing piles and waste dumps accumulated in the Province. Also in Manitoba, a private firm, Tantalum Mining Corporation of Canada Limited (Tanco), entered into a detailed study of by-product separation of marketable silica-feldspar mixtures from the currently discarded pegmatite-ore residues generated in the process of tantalum production.

Finland.—Finland's production of industrial minerals currently amounts to over 500,000 tons per year and of that total some 66,000 tons is feldspar, mostly high-potash microcline. The mineral is recovered by froth flotation from complex pegmatitic ores in mixtures with graphic granite at a new plant especially built for that purpose by Lojo Kalkverk AB, the European firm to employ that procedure in feldspar beneficiation.[5] An industrial journal published a detailed description of the equipment, flowsheets, and operating procedures in use at the alkverk mines and mill, which are situated on the island of Kimito (or Kemio) off Finland's southwest coast in the Gulf of Bothnia.[6]

Guyana.—Bauxite has been for many years the foremost source of Guyana's mineral export revenue, but recently there has been a notable upsurge of interest in the nation's known but almost entirely unexploited industrial minerals. The existence in Guyana of large deposits of high-grade kaolin, talc, kyanite, and silica sand has suggested the advantages of developing domestic glass and ceramics industries, either or both of which would offer an attractive outlet for feldspar, another of the industrial minerals occurring in commercial quantities within the national boundaries.[7]

India.—An industrial association published an updated version of an earlier report that, while emphasizing the mining industry of India and presenting a register of names and addresses of that nation's mineral producers, also outlined the international situation of 17 important industrial minerals—one of which was feldspar—with regard to world occurrences, production, reserves, and export/import trade.[8]

Jordan.—According to Mr. Nimri of the Jordanian Natural Resources Authority, Geological Research and Mining Department, even though phosphate rock is the only industrial mineral at present contributing to the national economy, at least five others including feldspar also exist in commercially exploitable quantities. Mr. Nimri further stated that a U.S. firm, Swindell-Dressler Co., has been authorized to conduct a study of the possibility of producing feldspar in Jordan for export to other Arab countries for use in glassmaking.

Sweden.—The Statsgruvor, the Swedish national mining authority, began a study to delineate the commercial possibilities of a large deposit of feldspar recently discovered in central Sweden by a private prospector. The potentially valuable ore body lies near the surface at Hällsjön, between Örebro and Motala, and may prove to be the largest occurrence of glass- and ceramic-grade feldspar in the country.

United Kingdom.—In terms of value, 1973 was a record year for the United Kingdom's foreign trade in nonmetallic minerals, with imports as usual far ahead of exports. Imports of feldspathic materials included 140,000 tons of feldspar, principally from Norway, Finland, Sweden, and Portugal with a total value of approximately $2.35 million, and 54,000 tons of nepheline syenite from Norway and Canada valued at $1.7 million. Exports consisted of 5,900 tons of feldspar valued at $0.26 million.

Domestic production ("China stone," "Cornwall stone") amounts to less than 3% of the United Kingdom's annual requirements for feldspathic materials, so that understandably a lively interest was aroused by the discovery a few years ago of a possible source of usable-grade feldspar in northwest Scotland.[9] The subsequent investigation, however, although confirming or increasing earlier estimates of the quantities of feldspar existing in the Durness pegmatite, raised serious doubts concerning the quality of the product that could be obtained—specifically, the iron content of the material was found to be excessive, and efforts to bring it down to an acceptable level were not successful. Increasing inability of domestic producers to supply even a modest part of the ceramic industry's feldspathic needs has now prompted a reexamination of the Durness material, with the tentative conclusion that at least a marginally satisfactory feldspar-quartz mixture can be prepared from it by a dry process involving high-intensity magnetic separation. A campaign was started for the purpose of accumulating a 500-ton test lot of such a product for industry evaluation.[10]

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, the People's Republic of China, Czechoslovakia, Romania, and the Territory of South-West Africa produce feldspar, but available information is inadequate to make reliable estimates of output levels.

[2] Described in source as lump feldspar; does not include nepheline syenite as follows, in short tons: 1972—177,542; 1973—220,793; 1974—224,430.

[3] Includes pegmatite.

[4] Chiefly labradorite.

[5] In addition, the following quantities of aplite and saba were produced: Aplite: 1972—501,069; 1973—547,665; 1974—539,670; Saba: 1972—1,336; 1973—NA; 1974—NA.

TECHNOLOGY

The 1974 research program of the Bureau of Mines included investigations of possibilities for improving the froth-flotation recovery of microcline feldspar (College Park Metallurgy Research Center, College Park, Md.) and for the recovery of potash feldspar from sulfide mill tailings (Tuscaloosa Metallurgy Research Laboratory, Tuscaloosa, Ala.). A Bureau report was published describing a system devised for obtaining feldspar in a usable form from a residue generated in the production of crushed stone and currently being discarded.[11]

An important modification of quarrying techniques was put into practice by some of the principal feldspar producers in 1973–74. The innovation emphasized the use of low-cost blasting materials of the ammonium nitrate, fuel oil type (AN-FO) in water-gel form and, in some cases, necessitated the purchase of heavier drilling machinery to make larger diameter blast holes to accommodate bulkier charges of those explosives.[12]

Most of the flotation schemes currently in use by feldspar producers involve conditioning the mineral with hydrofluoric acid prior to floating. Hydrofluoric acid, in addition to being expensive and hazardous, gives rise to pollution-control problems. The notable solubility of nearly all fluorides and fluosilicates generated during conditioning, makes it difficult or impossible to remove them from flotation-plant effluents that otherwise could conveniently be discharged into nearby watercourses. A patent was issued for a flotation method in which the customary addition of hydrofluoric acid is avoided by applying a mixture of beef-tallow amine acetate and an aromatic sulfonate to separate and collect feldspar from a pulp acidified to pH 2.0 to 3.5 with sulfuric acid.[13]

An increase of more than 40% in production capacity was achieved at two large feldspar-grinding plants in South Dakota without the installation of additional milling units. This remarkable improvement, along with important cost reductions for power, mill accessories, and maintenance, was credited to the replacement of the flint pebbles formerly serving as the grinding medium by rods consisting of a special preparation of dense and fine-grained crystalline alumina. As a further benefit, this innovation effectively circumvented the objectionable contamination of the product with silica that had resulted from the attrition of the natural pebbles.[14]

Preparation of frits for porcelain enamel provides a large outlet for high-quality feldspar, usually in the range of 10,000 to 30,000 tons per year in the United States. A journal article described the closely monitored operations carried out in the enameling plant of a major manufacturer of large household appliances.[15]

A patent was granted for a glassmaking

procedure in which the raw materials—silica, limestone, soda ash, and feldspar—are mixed and dampened with sodium hydroxide solution, briquetted, preheated with glass-furnace combustion gases, and then melted by a submerged-combustion procedure. It was claimed that in this manner there are achieved worthwhile reductions in fuel consumption and in capital costs of melting equipment, together with a substantial lowering of atmospheric pollution by sodium sulfate in the vented flue gases.[16]

In a process for which two patents were issued, aluminum is produced in the metallic state from iron-containing feldspar or other aluminous ores by chlorinating at over 700° C in the presence of a carbonaceous reductant to form gaseous aluminum monochloride, which upon subsequent flash cooling to 700° C disproportionates to yield metallic aluminum and aluminum trichloride. The aluminum metal is removed, and the still-hot gaseous aluminum trichloride is recycled to the original chlorination step.[17]

Speedy, precise, and repeatable analytical methods were described for analyzing high-silica and high-aluminosilicate materials, such as feldspar. These new methods bear little resemblance to the cook-book procedures, which were used by analysts many years ago.[18]

At least three important additions to the literature of feldspar became available in 1974, two dealing specifically with the feldspar minerals[19] and the other devoted to the closely related subject of the feldspathoids.[20]

NEPHELINE SYENITE

Nepheline syenite, a rock of igneous origin with a texture similar to that of granite, consists essentially of mixtures of nephelite with varying proportions of the alkali feldspars. Nepheline syenite found thus far in the United States has been of a quality suitable only for use as crushed stone. Canada, however, has an immense deposit at Blue Mountain, Ontario, from which two firms, Indusmin Limited, and International Minerals & Chemical Corp. (Canada) Limited, mine high-grade material that serves advantageously as an alumina-bearing ingredient in furnace feeds for glassmaking, as either a body component or a fluxing agent for ceramics, and increasingly in recent years as a filler for plastics, latex articles, paints, and paper.

In 1973, the last year for which estimates are available, Canadian production of nepheline syenite totaled approximately 576,000 tons with a value of $7.4 million. In 1974, Indusmin, already the larger of the two Canadian producers, announced plans for a major expansion of its Nephton mining and milling facilities that will provide substantially greater production capacity.

Other than Canada, only two countries are known to produce significant quantities of nepheline syenite—Norway with 177,500 tons in 1972 and 221,000 tons in 1973, and the U.S.S.R. where, although production figures are not released, the mineral is known to serve the customary applications of the glass and ceramics industries and also as a major source of cell-feed alumina for electrolytic aluminum plants.

U.S. imports of Canadian nepheline syenite, which were first reported in the mid-1930's, have increased in all but a few of the years since and now appear to be rising sharply. Starting at 10,000 tons per year or less in 1936, the figure reached 100,000 tons per year by 1955, 200,000 tons per year by 1964, 300,000 tons per year by 1968, 400,000 tons per year by 1971, and went beyond 500,000 tons per year in 1974. Under the present U.S. tariff schedule, imports of nepheline syenite, ground or unground, are admitted duty free.

The price range quoted for imported nepheline syenite in Ceramic Industry Magazine, January 1975, was from $11.75 to $31.45 per ton, depending upon grade, purity, grind, packaging, transportation, quantity of sales, and other factors. Price ranges for this commodity listed in Industrial Minerals (London), December 1974, were equivalent (with a minor degree of uncertainty because of the floating sterling/dollar exchange rate) to the following:

APLITE

Aplite is a fine-grained granitic rock containing quartz mixed with varying proportions of soda, lime-soda, or potash feldspars, any or all of which make it potentially useful as a raw material for manufacturing container glass. However, to be made acceptable for that purpose, the material occurring in most deposits must first be processed to eliminate most of the iron-bearing substances it usually contains. Japan with about 500,000 tons annually, is the world's foremost producer of aplite.

Aplite of glassmaking quality was produced in the United States in 1974 from two open pit mines in central Virginia. The Feldspar Corp. mined aplite ore near Montpelier, Hanover County, and removed iron from it by an electrostatic process. Sobin Chemicals, Inc. operated a mine near Piney River, Nelson County, and subjected the crushed aplite to a high-intensity magnetic separation to eliminate iron minerals.

Specific annual data on domestic aplite production, sales, and value have not been released for publication since 1962, when the output amounted to 140,000 tons, valued at $0.9 million. Domestic production reached an alltime high in 1974, but the corresponding total value was notably lower than in 1973.

The price range for aplite given in Ceramic Industry Magazine, January 1974, was from $12.70 to $13 per ton, but no quotation for aplite appeared in the January 1975 issue.

Ferroalloys

By Norman A. Matthews [1]

The overall structure of the domestic ferroalloy industry remained unchanged during 1974. Demand continued at capacity levels throughout most of the year. Ferromanganese capacity was reduced temporarily. New furnaces for silicon alloys went into operation and, together with reduced demand for silicon in cast iron and cast aluminum, eased the shortages of silicon alloys that had persisted during most of 1973. Ownership of two plants changed hands during the year, and construction was started on a completely new plant for silicon alloys in Alabama. Expansion projects were initiated for manganese alloys in West Virginia and ferrochromium silicon alloy in New York.

Ferroalloy exports declined, whereas imports continued to increase. Value of imports rose 83% as prices increased substantially during the year.

With the removal of price controls, a general increase in domestic prices occurred in late March, another in the third quarter, and another late in the year. In general prices doubled during the year, reflecting recovery from price controls and increased raw material and power costs.

Detailed information concerning utilization of individual elements in various alloy products can be found in the chromium, manganese, silicon, molybdenum, nickel, tungsten, and vanadium chapters.

[1] Includes briquets and fused-salt electrolytic.

[2] Includes silicon metal, silvery iron, and inoculant type alloys; does not include silicon alloys consumed internally.

[3] Includes chromium briquets, chromium metal, exothermic chromium additives, and other miscellaneous chromium alloys.

[4] Includes ferroboron, and other complex boron additive alloys, ferronickel, ferrotitanium, ferromolybdenum, ferrotungsten, ferrovanadium, spiegeleisen, ferrozirconium, and other miscellaneous alloys.

DOMESTIC PRODUCTION

The number of ferroalloy producers increased by 1 to 27, at yearend when Woodward Iron Co. of Mead Corp. sold its two plants; the Woodward, Ala., plant was acquired by Alabama Alloy Co., Inc., whereas the Rockwood, Tenn., plant was sold to Phillipp Brothers, Division of Englehard Minerals and Chemical Corp. A listing of producers, plant locations, products, and processes utilized is shown in table 3. Six producers specialized solely in ferrophosphorus as a byproduct of phosphorus production.

Demand for ferroalloys continued at high levels throughout most of 1974, but declined near yearend as inventories approached normal levels and steel and aluminum production rates declined. Overall production of 146 million tons of raw steel and 16.6 million tons of cast iron represented 4% and 8% declines, respectively, from the record tonnages in 1973, and demand for manganese and silicon alloys was reduced proportionately. Silicon demand was further reduced by the slack demand for aluminum castings from the dominant automotive and appliance markets. Manganese alloy supply was disturbed by conversion of two small blast furnaces to pig iron production, but shortages were minimized by substantial shipments from the Government stockpile. In contrast record production of stainless steel required record quantities of chromium, nickel, and molybdenum and, as a result, local shortages existed in some product forms, particularly in the second quarter. In retrospect there is substantial evidence that excess purchases were made by many firms, creating artificial shortages.

Several expansion projects were announced during the year. The most significant was the new ferroalloy plant to be built by Ohio Ferro-Alloy Corp. at Montgomery, Ala. This was the first ferroalloy plant to be built in the United States in 21 years. At an estimated cost of $20 million, and a capacity of 35,000 tons of silicon metal annually, the plant will consist of three furnaces for silicon metal and/or ferrosilicon, with the first furnace operational in late 1975. Of the total cost, $6 million represents the projected cost of pollution abatement equipment. Diamond Shamrock Corp. announced a $5 to $6 million expansion program to double capacity of bulk manganese to 17,000 tons annually, at the Chemetals Division plant in Kingwood, W. Va. Operation was projected for late 1975. Airco, Inc., announced a $15 million program at Niagara Falls to provide a second furnace of 36 kilowatt-ampere transformer rating and an additional 20,000 tons of capacity annually of ferrochromium silicon alloy by late 1976. The program includes rehabilitation of existing furnaces and provision of pollution abatement equipment.

Union Carbide Corp. announced development of a new tungsten mine and concentrator near Alamo, Nev., at a projected cost of $21 million. This will reduce U.S. dependence on imports from 60% to approximately 40%. The annual output rate of the mine will be second only to that of the Pine Creek, Calif., facility, to which the concentrates will be shipped for conversion to ammonium paratungstate. The new Tempiute mine and concentrator will process approximately 1,000 tons of ore per day.

[2] Includes zirconium alloys, ferrosilicon magnesium, calcium silicon, and miscellaneous ferroalloys.

CONSUMPTION AND USES

Steel production of 146 million tons involved a reported consumption of 1,168,860 tons of ferromanganese of all types, essentially equal to consumption in 1973 when a record steel production of 150.8 million tons was achieved. Steel product mix is gradually changing with larger volumes in the high-strength low-alloy (HSLA) types which, almost universally, are higher in manganese. However, it appears that the efficiency of manganese recovery is gradually deteriorating and is undoubtedly influenced by basic oxygen furnace practices which probably do not achieve a fully reduced slag condition prior to final manganese additions. Silicomanganese consumption was also higher in 1974 than in 1973.

Silicon alloy consumption totaling 987,902 tons in 1974 declined considerably from that consumed in 1973, and correlated more closely with the approximate 14% and 20% decline respectively, in cast iron and cast aluminum production. The ferrotitanium figure for 1974 is substantially lower than that reported for 1973; the 1973 consumption figure was overstated and should have been 5,143 tons. Corrected distribution of ferrotitanium usage in 1973 reduced the carbon steel category to 981 tons, the alloys category to 1,166 tons, and other uses category to 142 tons. Ferrotitanium usage continues to grow as would be expected with growth of high-strength low-alloy steel tonnages.

Consumption of ferrochromium, ferronickel, and ferromolybdenum was at record levels correlating with record production of stainless and tool steels. Similarly the increase in consumption of ferrovanadium and ferrocolumbium reflects continued growth in shipments of high-strength low-alloy steels. Vanadium and tungsten consumption for tool steels, in the ferroalloy form, declined in 1974 compared with that of 1973. Nickel consumption as ferronickel continued to increase rapidly as world supply increased.

Table 4.—Consumption by end use of ferroalloys as additives in the United States in 1974

(Short tons of alloys)

Alloy	Stainless steels	Other alloy steels	Carbon steels	Tool steels	Cast irons	Superalloys	Alloys (excludes alloy steels and superalloys)	Other uses [1]	Total

[4] Includes melting base self-reducing tungsten.

[5] Includes other vanadium-carbon-iron ferroalloys.

STOCKS

Producers' stocks declined overall during 1974 and were particularly low in manganese and chromium alloys at yearend. Consumer stocks of manganese and chromium alloys had recovered to a normal level by yearend, whereas consumer stocks of silicon alloys were much higher than normal. Ferronickel consumer stocks also increased substantially during the year.

Table 6.—Stocks of ferroalloys held by producers and consumers in the United States, December 31, 1974

(Short tons)

	Producer		Consumer	
	1973 (gross weight)	1974 (gross weight)	1973 (gross weight)	1974 (gross weight)
Managanese ferroalloys [1]	122,098	84,873	180,242	298,048

Ferrocolumbium	340	463	728	860
Total	611	767	10,930	15,541

r Revised. W Withheld to avoid disclosing individual company confidential data.

[1] Includes ferromanganese, silicomanganese, spiegeleisen, and manganese metal.

[2] Includes ferrosilicon, silvery iron, silicon metal, and miscellaneous silicon alloys.

[3] Includes other chromium ferroalloys and chromium metal.

[4] Includes other titanium materials.

[5] Includes other phosphorus materials.

[6] Includes calcium molybdate.

PRICES

Prices of all ferroalloys increased several times during the year, with the initial round of increases following price decontrol late in March. In general manganese alloy prices increased in late March, in the second quarter of the year, and in December. Chromium and silicon alloy prices increased in late March, in the third quarter of the year, and in December. In general terms, prices doubled during 1974 as the following illustrates:

Alloy and units [1]	Price, year-end 1973	Price, year-end 1974
Standard 78% ferromanganese, dollars per gross ton	200	400–440
Low-carbon ferromanganese, 0.05% maximum carbon	32.5	59.5
Charge chromium (64% to 69%)	20.0	50–53
Low-carbon ferrochromium, 0.05% maximum carbon	33.0	83
Ferrosilicon, 75%	22.35	36.5–38.5
Silicon metal, 1% maximum iron	23–26	40–55
Ferronickel	138	197
Ferrovanadium	419	555

[1] Cents per pound contained unless otherwise indicated; prices as quoted in American Metal Market.

Price increases were attributed to rising costs during the period of price controls, and 1974 cost increases for ore and other raw materials, power, and labor. Perhaps of greatest importance was the expressed necessity of improving profits to generate capital for expansion and modernization of facilities.

FOREIGN TRADE

Quantity of U.S. exports of ferroalloys in 1974 declined 45% compared with that of 1973, but value increased to $37.6 million as much higher unit prices applied universally. Canada and Japan remained the largest export customers. Most of the decline was in chromium and silicon alloys and ferrophosphorus. Only ferromolybdenum exports showed a substantial increase when compared with that of 1973. The overall quantity exported in 1974 was 46,168 tons.

In general, imports continued to increase during 1974 and reached a total of 945,593 tons valued at $388.6 million, representing a 17% increase in tonnage and an 83% increase in value compared with 1973 totals. The largest tonnage increases were recorded for high-carbon ferromanganese, ferrosilicon manganese, and 75% ferrosilicon. The largest percentage increases in imports occurred in some of the smaller volume items such as low-carbon ferromanganese and ferrotitanium. Imports of ferronickel also increased substantially and the value thereof was the highest of any single commodity. A new category, entitled Base Metal Alloys, Unwrought, was added to table 8. This category, for 1974, predominantly reflects imports of silicon metal of 94% to 97% silicon.

The Republic of South Africa remained the dominant exporter of ferroalloys to the United States in 1974, principally manganese and chromium alloys, totaling 209,000 tons, followed by France with 195,000 tons, Norway with 74,348 tons, Japan with 65,481 tons, Yugoslavia with 42,491 tons, Sweden with 35,065 tons, and Brazil with 19,703 tons. In the case of 75% ferrosilicon, 25 countries were listed as countries of origin; high-carbon ferromanganese, the largest tonnage commodity, was imported from 13 countries, but 6 countries accounted for 96% of the tonnage imported.

In chromium alloys, shipments to the United States ranked by value were from: (1) the Republic of South Africa; (2) Yugoslavia; (3) Southern Rhodesia; and

(4) Japan. In manganese alloys, receipts were from: (1) France; (2) the Republic of South Africa; (3) Japan; and (4) Norway. The value of silicon alloys imported almost tripled to $72 million, whereas the tonnage increased by 47% compared with 1973 figures. In silicon alloys, imports by value were from: (1) Norway; (2) Yugoslavia; (3) France; and (4) Sweden.

Prices of ferroalloys throughout the market economies of the world increased rapidly during 1974. Prices of imported alloys also increased rapidly in parallel with domestic prices. In general, import prices (not including transportation) were lower than domestic prices throughout the year. The exception was 50% ferrosilicon alloy. For this alloy average import prices, not including transportation, exceeded domestic prices throughout the year.

[2] Principally ferrocolumbium.

[3] Principally silicon metal of 94% to 97% silicon.

WORLD REVIEW

Table 9 lists ferroalloy production in the world by country and furnace type for the years 1972 through 1974 from the most reliable sources. Production increased overall as the steel companies of the world operated generally at capacity levels, at least through October. The total world production, reported and estimated, of 12.4 million tons in 1974 represents a 4.7% increase over that produced in 1973. Countries which showed substantial increases in production in 1974 included: West Germany (blast furnace alloys), Canada, Brazil, Norway, Yugoslavia, the Republic of South Africa, and Japan.

Australia.—Tasmanian Electro Metallurgical Co. Pty. Ltd., a subsidiary of Broken Hill Proprietary Co. Ltd., announced an expansion at Bell Bay, Tasmania to double capacity to 160,000 tons annually with two new furnaces, one each for ferromanganese and ferrosilicon. The new installations, including an ore processing facility, were estimated to cost $29 million, with startup scheduled for late 1975. Hydroelectric power will be provided from the Pieman Power Project.

Consolidated Gold Fields Ltd., with two other Australian partners and the Norwegian Ferro Silicon Producers' Association (Fesil), announced a new ferrosilicon plant to be constructed at Electrona near Hobart, Tasmania. Two furnaces were planned, the first for ferrosilicon production at an annual rate of 50,000 tons for operation in 1976 and the second producing silicon metal and scheduled for operation in 1977. The products will be exported, principally to Japan.

Brazil.—Brejui Mineração Metalurgia announced that a ferrotungsten plant of 200 tons annual capacity would be constructed by 1976, after a pilot plant campaign to be completed in early 1975. The plant will convert scheelite concentrates of 70% WO_3 content produced by the partner company Mineração Tomaz Salustino. One half of production is scheduled for export to Japan.

Cia. Brasileira de Mineração de Cáleio in Minas Gerais started up a 13.5 megavolt ampere furnace producing ferrosilicon at yearend. Several other Brazilian ferrosilicon producers have also announced expansions totaling 100,000 tons annually by 1979. These include Alumínio do Brasil S.A. 12,000 tons by 1978; Cia. de Ferro-Ligas da Bahia, S.A. 16,000 tons by 1976; Ligas de Alumínio S.A. 19,000 tons by 1976; Cia. Paulista de Ferro-Ligas, 7,000 tons by 1976; Eletrosiderúrgica Brasileira S.A. 23,000 tons by 1976; and Industria e Comercia, 16,000 tons by 1978.

Canada.—SKW Electro-Metallurgy Canada, Ltd., a subsidiary of Suddeutsche Kalkstickstoff-Werke A.G. of West Germany, announced contracts for a $40 million ferroalloy plant to be constructed in Becancour, Quebec. The plant, with 120 megawatt capacity, is designed for a combined capacity of 52,000 tons annually of ferrosilicon and silicon metal. Operation was scheduled for early 1976. Eighty percent of the output will be exported to Europe and the United States.

Northwest Mining Co., a subsidiary of Climax Molybdenum of Canada, delineated a large scheelite ore deposit in the Yukon Territory. The deposit, near the Northwest Territories border at MacMillan Pass, has reserves of at least 30 million pounds of tungsten. A large annual output is projected within 10 years.

Gabon.—The Gabonese Ferroalloy Co. (SOGAFERRO) was established in 1974. Interest in the company is held by the Government of Gabon (10%), Gabonese mining companies (30%), Japanese companies (25%), and the remainder by various French, Norwegian, Belgian, and Italian organizations. The Government has contracted with an international consortium (Belgian, French, West German, Dutch, Italian, and Spanish) to build a 410-mile railroad from the iron ore deposits at Mekambo to the ports of Libreville and Franceville at a cost of $325 million, with completion projected in 1981. Ferromanganese production is not anticipated prior to 1980.

Japan.—Japan produced 2,499,000 short tons (2,267,000 metric tons) of ferroalloys in 1974, exceeding the volume produced in the United States. Japan exceeded the United States in the production of ferromanganese, ferrochromium, ferronickel, silicomanganese, and ferrotungsten. Several expansion or replacement projects were announced during 1974. Nippon Refining and Concentrating Co. announced a new 30 megavolt-ampere furnace at Kohma with a capacity of 16,000 tons of ferrosilicon annually for operation in early 1976 at a cost of $2 million. Low power costs are expected from a captive powerplant. Japan Metals and Chemicals Co., Ltd., announced the addition of two 25 megavolt-ampere ferrosilicon furnaces at the Matsukawa plant, with a total capacity of 34,000 tons annually. The first was to be in operation late in 1975 and the second in 1976. Electrical energy will be supplied from an enlarged geothermal powerplant. Ube Denki Kaguku, a subsidiary of Ube Industries and Nissho-Iwai, planned to expand ferrosilicon production from 25,000 to 55,000 tons annually with installation of a 30 megavolt-ampere furnace by late 1975.

Norway.—Elkem-Spigerverket A/S planned a fourth ferrosilicon furnace at the Salten plant with a 35 megavolt-ampere transformer capability and a capacity of 30,000 tons annually, for operation in 1976. Cost was estimated at $21.5 million. It is understood that this furnace, and perhaps a second at the Halsland location, constitute the last expansions of ferroalloy capacity in Norway compatible with the overall allocation of energy to ferroalloys among the high electrical energy-consumption industries.

Philippines.—Maria Cristina Chemical Industries, the existing ferroalloy producer, announced an expansion at the Iligan site on Mindanao. The new furnace, with a capacity of 17,000 tons of ferromanganese annually, will be completed in late 1975 at a cost of $4.7 million. Nippon Denko Co. and C. Itoh & Co. of Japan formed a joint venture with the Laurel Foundation of the Philippines for a ferrosilicon plant, also at Iligan. The company which was established by the joint venture, Electro Alloys Corp., planned to operate one furnace initially, starting in 1976, with an annual capacity of 10,000 tons. Total production will be exported to Japan.

South Africa, Republic of.—Parliament passed new tax incentives for ore beneficiation and conversion, including production of ferroalloys. Extra investment allowances of 20% for machinery and 15% for buildings were incorporated into the law. Feralloys Ltd., the ferroalloys subsidiary of Associated Manganese Mines of S.A. Ltd., announced a $15 million expansion project for an additional manganese furnace at the Cato Ridge plant and a charge ferrochromium furnace at the Machadodrop plant at Fairview in the eastern Transvaal. The new furnaces will raise annual manganese and chromium alloy capacities by 50,000 and 30,000 tons, respectively, when in full operation in 1976.

Turkey.—Etibank, the state investment company, planned to install two 17 megavolt-ampere Japanese furnaces for high-carbon ferrochromium with production to start in 1976. Ore will be supplied locally from the Mardin area and power will be from the Kaban dam, completion of which has been delayed.

U.S.S.R.—The Government sought tenders in September from the United States and Europe for equipment and technology to produce 1,200,000 tons of ferromanganese, 320,000 tons of ferrochromium, and 60,000 tons of polycrystalline silicon annually. Associated were mining facilities for 2,300,000 tons of manganese ore concentrate and 2,150,000 tons of chromium ore concentrate annually. U.S. ferroalloy producers have been involved in detailed studies on some or all of the facilities required.

Upper Volta.—Eleven Japanese ferroalloy producers and trading firms, of which the principals were Japanese Metal Corp., Mitsui Corp., and Nippon Denko KK, together with Union Carbide Corp., French Society Manganese, and the German Exploration and Bergwerke, announced plans to develop the manganese ore deposits at Tambao. Shipments of 625,000 tons annually are anticipated by 1980 with over 50% alloted to the Japanese partners.

Venezuela.—Hevensa announced expansion of its ferrosilicon plant from 30,000 to 50,000 tons annually with completion in 1977. The project includes upgrading of existing facilities. Venbozel, a joint venture of the Government's Corporacíon Venezolana de Guyana and Nobel Bozel S.A. of France, began construction during the year of a 52 megavolt-ampere ferrosilicon furnace and plant structure in the Orinoco region. Completion of the first furnace is now projected for 1977 with a second furnace to follow in 1978. A third furnace, involving a joint venture with Nissho-Iwai and Mitsubishi Corp. of Japan, is also planned. Power will be provided from hydroelectric facilities in Guyana.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, the People's Republic of China and North Korea are known to produce ferroalloys, but output of these materials are included in estimates for pig iron in the iron and steel chapter, therefore they have been omitted here to avoid duplication. East Germany also is known to produce ferroalloys, but it is not clear from source publications whether output has been included together with that of pig iron and steel. Also Colombia, Greece, Luxembourg, Peru, Venezuela and Southern Rhodesia may produce ferroalloys and output, if any, is included with pig iron in the iron and steel chapter.

[2] Blast furnace ferroalloy production by Australia, Canada and the United States included under electric furnace output.

[3] Blast furnace ferromanganese, ferrosilicon and spiegeleisen only; other blast furnace ferroalloys are included in the pig iron production table in the iron and steel chapter.

[4] Includes electric furnace ferroalloys, if any are produced.

[5] In addition to the countries listed, the United Kingdom and the U.S.S.R. are known to have produced electric furnace ferroalloys and Romania may have produced some electric furnace ferroalloys, but output is not reported and no basis for estimation is available.

[6] May include small quantities of blast furnace ferroalloys, if any are produced.

[7] Year ended November 30 of year stated.

Yugoslavia.—Financing has been arranged for a $300 million ferronickel project based upon lateritic ores in the Kavadarci area of Macedonia. Arthur G. McKee Co. prepared the proposals which contemplate 16,000 tons of nickel in 60,000 tons of ferronickel annually with coproduction of 600,000 tons of iron concentrates. The ore deposits total 110 million tons of which 2.2 million tons will be processed annually. Feni Kombinat is the Yugoslavian company involved and has projected initial production in 1979.

TECHNOLOGY

The most active areas of research in iron and steel production that influenced the consumption of ferroalloys or the types of ferroalloys required were: (1) high-strength, nonheat-treated steels with emphasis on maximum toughness and/or ductility; (2) desulfurization of molten pig iron by magnesium or other additives; (3) desulfurization of cupola iron in the production of ductile (nodular) iron; and (4) new powder metallurgy processes. The evolution of optimum practices for HSLA steels continued with the most prominent fields of application principally Arctic gas pipelines and automotive uses. For such steels the unique properties are conferred by columbium and/or vanadium, rare-earth elements that influence inclusion morphology, and titanium. Demands on process technology include very low phosphorus and sulfur levels, minimum inclusion content, and controlled finish rolling temperatures.

In the United States and Western Europe considerable experimentation was in progress on the use of magnesium and other additives for desulfurizing molten blast furnace iron. Battelle Memorial Institute established a multisponsor program involving 14 U.S., European, Japanese, and Brazilian steel companies. Similarly, the use of magnesium wire injection for nodularizing cast iron received widespread attention as a result of a summary paper presented at the 1975 American Foundrymen's Society annual casting congress.[2]

United States Steel Corp. announced the newly patented "loose-pack" powder metallurgy process which involves: (1) vibratory packing of prealloyed powders in a mold; (2) sintering; and (3) hot forging to achieve near-theoretical density.[3] A disposable mold, constituted from paper, is used, and the process avoids the high costs of powder metallurgy presses. Of significance to ferroalloy interests is the likelihood that such a process, utilizing prealloyed powders, will alleviate the necessity of producing small quantities of special additive alloys in powder form.

Methods of pretreating the charge materials for submerged-arc furnace smelting continued to be studied. Representatives of Showa Denko K.K. of Japan presented a paper at the First International Ferro-Alloys Congress (INFACON '74) on pelletizing of the chromite ore feed for the production of charge chromium. Considerable improvements in furnace operability and productivity and a decrease in power consumption were reported. U.S. patent 3,847,114 was issued to the same company in November.

A journal article reported beneficial effects from high phosphorus in cast iron in reducing cleaning costs attributed to core and mold penetrations by the molten cast iron. Raising phosphorus levels from 0.03% to 0.09% reduced cleaning costs 35% to 40% on test castings simulating actual typical castings.[4]

A project at the Rolla Metallurgy Research Center of the Bureau of Mines evaluated methods for reclaiming metallics from electric furnace flue dusts, mill scale, and grinding swarf.[5] Pelletizing the dusts from a stainless steel production mill with a reducing agent and melting in an induction furnace formed an alloy containing 10% to 20% chromium, 6% to 12% nickel, and 55% to 65% iron, plus lesser amounts of manganese and molybdenum. Similarly pelletizing of such materials and feeding to a small submerged-arc furnace would be expected to improve recoveries; with proper temperature control significant reduction of silicon probably could be avoided.

The INFACON '74 was held in Johannesburg, South Africa, in April 1974 and was attended by 300 delegates from 22 countries. Thirty-two papers were presented under categories designated as burden preparation, specific processes, electric smelting furnaces, fundamental aspects, pollution control, and application and trends. The complete proceedings, including discussion, comprise the most comprehensive recent reference on trends in ferroalloy technology.[6]

Fluorspar

By H. B. Wood [1]

The United States continued to rely on imports to supply about 88% of its reported demand for fluorspar. About 70% of reported demand was supplied by imports from Mexico. Domestic production decreased 19% from 1973 to 201,000 tons. U.S. reported consumption increased 13% from 1973, and apparent consumption decreased 6%. Consumers inventories increased 31%, to 431,000 tons of both acid-grade fluorspar (acid-spar) and metallurgical-grade fluorspar (met-spar). No sales were made from U.S. government inventories which remained at 1.3 million tons of combined acid-spar and met-spar. During 1974, U.S. imports of all grades of fluorspar increased 10% to 1,336,000 tons, synthetic and natural cryolite imports remained the same at about 20,000 tons, and imports of 70% hydrofluoric acid (HF) increased 3% to 32,500 tons.

Prices increases ranging from 5% to 9% were reported for various grades of fluorspar. All increases were predominantly the result of inflationary pressures, since there was no shortage throughout the world, and no cartel was known to be controlling prices.

Effective April 1, 1974, Pennwalt Corp. increased its interest in Ozark-Mahoning Co. from 35% to 100%. This made Pennwalt, which is a major importer of fluorspar and a manufacturer of hydrofluoric acid, the largest producer of fluorspar in the United States.

The Trade Act of 1974 became effective at yearend. This act authorized the President of the United States to enter into trade agreements with foreign countries, whereby the duties on imported materials could be eliminated or reduced by 60%. Fluorspar is one of the commodities subject to the provisions of the act. The effect of this act will not be known until sometime in 1975 or 1976.

In the Sweetwater District southwest of Knoxville, Tenn., U.S. Borax and Chemical Co. announced the discovery of about 50 million tons of fluorspar ore assaying 15% to 30% CaF_2.

Consumption of met-spar by iron and steel companies increased from 45% to 47% of the U.S. total, and the consumption of acid-spar to make hydrofluoric acid for use by the chemical and aluminum industries decreased from 52% to 51%.

In September, scientists predicted great danger to man's health if the escape of chlorofluorocarbons from aerosol sprays and refrigerants into the atmosphere was allowed to continue. Temporary and complete bans on the use of chlorofluorocarbons were proposed by State and Federal legislative representatives resulting in an immediate reduction in the demand for acid-spar, which was used to make hydrofluoric acid for manufacturing fluorocarbons.

Mexico, the world's largest producer of fluorspar, continued to supply the largest portion of U.S. imports, 74% in 1973 and 80% in 1974; Spain and Italy supplied most of the remainder. The largest fluorspar importing countries were the United States, Japan, the U.S.S.R., West Germany, and Canada. The largest exporting countries, in order of shipping volume, were Mexico, Thailand, Mongolia, Spain, the People's Republic of China and the Republic of South Africa. World production was about the same in 1974 as in 1973, and was only 2% greater than it was in 1972.

---

[1] Geologist, Division of Nonmetallic Minerals.

r Revised.

[1] Apparent consumption includes finished shipments, plus imports, minus exports, and plus or minus stockpile adjustments.

Legislation and Government Programs.—The "omnibus bill" (OMB No. 5) that was submitted to the U.S. Congress in April 1973 had not, at yearend 1974, resulted in the sale of any of the General Services Administration (GSA) stockpile of fluorspar. The U.S. Office of Emergency Preparedness established a stockpile objective of 159,000 tons of met-spar, and presented a plan to dispose of 1,142,800 tons of excess met-spar and acid-spar combined. Any further action on this bill does not appear imminent because in January 1975, the Joint Congressional Committee on Defense, which is responsible for reviewing programs authorized by the Defense Production Act, advised against the sale of strategic materials from government stockpiles.

Title 1, of the Trade Act of 1974 that was signed in December, authorized the President for a period of 5 years, to enter into trade agreements whereby import duties could be reduced or eliminated. The duty on acid-grade fluorspar could be eliminated and the duty on metallurgical-grade fluorspar could be reduced 60%. Under Title 5, Generalized System of Preferences, the President was authorized to suspend the import duty on fluorspar for the most-favored, less-developed countries; but after hearings were held, fluorspar was eliminated from the list of eligible minerals under this act.

The Government, through the Office of Minerals Exploration, normally can grant loans up to 50% of approved costs for exploration of eligible deposits of fluorspar, but in Fiscal Year 1975 the administrating agency, the U.S. Geological Survey, was not allocated funds for this program.

Fluorspar was subject to a Federal depletion allowance of 22% domestic and 14% foreign.

U.S. fluorspar-import duties effective through 1974 were as follows:

Item	Number	Rate of Duty		Statutory rate per long ton
		Long ton	Short ton	
Acid-grade (+97% CaF_2) -	522.21	$2.10	$1.87	$5.60
Metallurgical-grade (−97% CaF_2) ---------	522.24	8.40	7.50	8.40

DOMESTIC PRODUCTION

During 1974, U.S. shipments of finished fluorspar decreased 19% to 201,000 tons. About 38% was acid-spar and 62% was met-spar, which included gravel-spar, ceramic-spar, and briquets. About 76% of the production was in Illinois, mainly in Pope and Hardin Counties. The rest was shipped from mines in Montana, Texas, Nevada, Kentucky, Utah, Colorado, and New Mexico, in order of volume.

During 1974, 23 mines and 9 flotation and heavy-media plants operated, but only 4 plants operated full time. Two mines were closed during the year, one in New Mexico and the other in Utah. Effective April 1, Pennwalt Corp. purchased full ownership of Ozark-Mahoning Co.; Pennwalt previously owned 35% of the company. As a result of the merger, Ozark was assigned management of all mining operations including Pennwalt's fluorspar-briquetting plant at Brownsville, Tex., and its La Consantina fluorspar mine in San Luis Potosí, Mexico. At Cowdrey, Colo., Ozark-Mahoning Co. shipped ore from inventory but did not operate its mines or flotation plant. In New Mexico, Mining and Milling Co. of America placed its new flotation plant, located south of Hachita, on standby basis while the firm explored for more ore at the Volcano mine.

In Kentucky, Cerro Spar Corp. went onstream in April with its new 55,000-ton-per-year output capacity froth flotation plant located near Salem. For the remainder of the year, the plant was operated on a part-time basis as development of the Babb-Barnes mine continued. This newly developed ore deposit occurs at depths of 300 to 700 feet. The operation was controlled by a joint venture; 70% owned by Cerro Spar Corp., a wholly-owned subsidiary of Cerro Corp., and 30% by Frontier Resources Inc., Denver, Colo., and J. Fred Landers, Nashville, Tenn. In Kentucky, Minerva Oil Co. reopened the Wheatcroft, Tabb, and Brown-Ward shafts to the Lafayette ore body and started limited production.

In Texas, mining operations were continued by D & F Minerals Co. in the Christmas Mountains on the north edge of Big Bend National Park. In Utah, Willden Fluorspar Co., Spor Brothers, and U.S. Energy Corp. continued small shipments. In Nevada, J. Irving Crowell, Jr., & Son and Spor Brothers, near Beatty, Nev., continued shipments—Crowell to a steel company and Spor Brothers to a cement company. Bailey Fluorspar Co. continued to operate buying stations at Marathon, Tex., and Delta, Utah, where they purchased custom ore and screened and graded it for the met-spar market.

In Illinois, both Ozark-Mahoning and Minerva Oil carried on a continuous exploration and development drilling program, thereby enabling development of sufficient reserves to replace annual production. Minerva continued to develop the Spivey mine, but it was not expected to be in full production until 1975. A shaft was being sunk to 685 feet and the planned depth of the main station was about 600 feet. The ore will be trucked about 10 miles to the Minerva flotation plant at Cave-in-Rock, Ill.

U.S. Borax and Chemical Co., a subsidiary of Rio Tinto Zinc Corp., Ltd., continued exploration drilling on its fluorspar-barite prospect in the Sweetwater district, southwest of Knoxville, Tenn. Major discoveries have been announced in McMinn, Monroe, and Loudon Counties which could total 50 million tons of fluorspar ore assaying 15% to 30% CaF_2. Allied Chemical Co. continued active exploration of many fluorspar prospects in New Mexico and Colorado. Ozark-Mahoning Co. performed a limited amount of exploration drilling on unpatented claims in northern Colorado.

Reynolds Mining Co. at Eagle Pass, Tex., operated a fluorspar froth flotation plant which has a rated output capacity of 90,000 tons annually of acid-spar. Reynolds continued its practice of buying fluorspar ore of variable grades in Mexico, of impounding it under general imports (tariff duty free), of processing the ore in the flotation plant, and of producing quality acid-spar, containing 97% plus CaF_2. Then the acid-spar was passed through U.S. Customs as imports for consumption. Most of the 1974 output was used by Reynolds to make electrofluxes for its alumina smelting operations, but some was sold on the open market. Although this plant was located in the United States it did not process U.S. ore; therefore, it is not listed in table 2.

Table 2.—U.S. fluorspar-producing mines and mills in 1974

State	Company	Mines	Plants[1]
Colorado	Ozark-Mahoning Co	Cowdrey[2]	Flotation and briquet.
Illinois	Hastie Mining Co	Spar Mountain	None.

Do	Willden Fluorspar Co	Lost Sheep	Do.
Do	Spor Bros	Fluoride	Do.

[1] Of the nine plants shown only four were full time operations.
[2] Output from inventory only.

Seven fluorspar briquetting or pelletizing plants operated during 1974. These plants furnished fluxing material for the iron and steel industry and cannot be classified either as producers or end use consumers of fluorspar. They were beneficiators or convertors of fluorspar ore into a more usable product. The compaction blend contained fines, gravel, or filter cake containing from 35% to 97% CaF_2. Additions of lime, limestone, and oxides of manganese, iron, aluminum, titanium, boron etc., as well as cinders, were made to fulfill customer requirements; consequently, the CaF_2 content of the primary blend was diluted by a factor of up to at least 1.5.

The briquetting industry operated at 60% of capacity during 1974, and produced 277,000 tons of briquets valued at approximately $20 million. Operating data for 1974 were as follows:

	Tons	Average CaF_2 content percent
Total capacity	460,000	--
Fluorspar processed, all kinds	185,000	78
Fluorspar briquets produced	276,700	58
Fluorspar briquets shipped	282,600	58

The market demand for fluorspar briquets decreased during the final quarter and stocks increased. About 90% of the fluorspar made into briquets was imported, mainly from Mexico. The location of U.S. fluorspar briquetting plants in operation during 1974 are as follows:

State	City	Company
Illinois	Rosiclare	Ozark-Mahoning Corp.[1]
Indiana	East Chicago	National Briquet Corp.
Michigan	Dearborn	Mercier Corp.
Pennsylvania	Duquesne	Cametco, Inc.
Texas	Brownsville	Delhi Foundry Sand Co., Oglebay Norton Co. and Ozark-Mahoning Co.

[1] Subsidiary of Pennwalt Corp.

Two companies each operating two plants made end use building-block-size bricks. Cleveland Flux Co. made a steel furnace liner brick containing about 93% CaF_2 that acted as a flux and metal purifier. Glen Gery Corp. made a building brick which contained about 5% of 95% CaF_2 and is used for outside wall construction. Reportedly, the fluorspar fused the vanadium salts contained in the brick thereby preventing leaching.

The fluorspar supply picture is incomplete without including the supply of fluorine derived from byproduct hydrofluosilicic acid (H_2SiF_6), which is recovered from the wet-process production of phosphoric acid. During 1973 and 1974, about 58,000 tons annually of hydrofluosilicic acid was recovered from phosphoric acid plants. Theoretically, the 79% fluorine content of this acid is equivalent to about 90,000 tons of acid-spar that would have been used to make hydrofluoric acid for the chemical and aluminum industries and for fluoridation of public water supplies.

About 57% of the H_2SiF_6 was used to make fluoride salts for use in aluminum potlines, 28% was used for other chemical products, and 15% was used in water fluoridation. The H_2SiF_6 supply is expected to increase slowly as new phosphoric acid plants are built in Florida and North Carolina, but the market has not developed rapidly.

[1] Total value as reported by mine producers.

[2] Mine stocks as of Dec. 31.

Reserves and Resources.—U.S. minable reserves total about 17 million tons of 35% CaF_2 or equivalent, containing about 2.6 million tons of fluorine. Another 11 million tons of submarginal-grade material have been delineated in Colorado, Idaho, Illinois, Kentucky, New Mexico, and Tennessee, which, because of high mining and freight costs, are classified as identifiable resources. Another 68 million tons of inferred resources are scattered throughout 13 States as shown in table 5. U.S. resources occur mainly in Illinois, Tennessee, Alaska, Colorado, Kentucky, Idaho, and New Mexico. The known reserves occur within localized mining districts as small isolated ore bodies or clusters of ore bodies, and as irregularly shaped pods, mantos, veins, or breccia zones. The mined rock generally contains from 25% to 70% CaF_2, variable amounts of gangue calcite and quartz, and minor amounts of barite, sphalerite, and galena which may be recovered as a byproduct. Most of the deposits are of less than 500,000 tons, but a few larger low-grade deposits, containing millions of tons, may become commercially attractive if they can be mined economically and if the ore is amenable to beneficiation.

[1] Totals used by U.S. Geological Survey and agreed on by the U.S. Bureau of Mines.

[2] Total equivalent tonnage at 35% CaF_2 and then rounded. Figures quoted by the U.S. Bureau of Mines.

A resource of 50 million tons of fluorspar, ranging from 15% to 30% CaF_2 has been developed in the past 2 years by U.S. Borax and Chemical Co. in the Sweetwater district about 40 miles southwest of Knoxville, Tenn. This ore occurs in scattered replacement-type deposits in a limestone host rock and contains zinc and barium minerals which could be recovered as a byproduct. In New Mexico another new resource, the Salado deposit, containing 2½ million tons, assaying 21% CaF_2 and containing about 50% SiO_2, was delineated between 1971 and 1973. The Lost River Mining Co. deposit on Seward Peninsula, Alaska, which contains about 32 million tons of material averaging about 17% CaF_2, is still classified as a resource. Evaluation and development work continued into 1974 on this deposit.

An extensive exploration program by Allied Chemical Corp. in New Mexico from 1971 to 1974 resulted in an increase in the minable reserves and resources of this State, and an equally extensive exploration program by NL Industries, Inc. in the Challis, Idaho, area in 1972–74 increased the reserves and resources of Idaho.

In 1974, a reevaluation of western U.S. fluorspar reserves was made because, at yearend 1973, Ozark-Mahoning Co. had closed down its Northgate, Colo. mines and mill, Allied Chemical Corp. had closed its Boulder, Colo. mill and Burlington mine, and Tonto Mining and Milling Co. Inc. had closed down its small mine and mill near Pumpkin Center, Ariz. Also, during 1974, Mining and Milling Co. of America closed down its new mine and mill south of Hachita, N. Mex. Because of the decreasing production, and because estimated reserves for the western States had been reported the same for years, a Bureau of Mines field survey was carried out to reevaluate fluorspar reserves. As a result, notable reductions were made for Arizona, Nevada, Utah, and Colorado. Because mining, milling, and freight costs had increased so much, these mines were no longer competitive with imported fluorspar from Mexico. Only two mines were known to have closed because they were nearly out of economically minable ore.

Reserves estimates for the Illinois-Kentucky district have stayed the same and withstood continuing mining, mainly because operators have maintained continuous exploration programs. Also, improved beneficiating methods have been introduced to recover byproducts such as zinc, lead, and barite, and heavy-media preconcentration at or near the mine mouth has permitted operators to lower their mining grade cutoff. Consequently, the average ore grade has been reduced to about 30% CaF_2, and reserves for some of the deposits have been increased.

CONSUMPTION AND USES

U.S. consumption, as reported by over 300 consumers, increased 13% from 1,352,000 tons in 1973 to 1,525,000 tons in 1974; however, the apparent consumption as determined from the balance of production, imports, exports, and inventory adjustments indicated a 5% decrease from 1,509,000 tons in 1973 to 1,429,000 tons in 1974. The difference of about 90,000 tons between 1974 reported and apparent consumption may have been caused by consumer stockpile adjustments or inclusion of foreign material during production of met-spar briquets. As previously mentioned, the briquetting industry reported consuming 187,000 tons of primary fluorspar and shipping about 283,000 tons of briquets.

The major consuming industries were iron and steel, 47%; chemicals, 28%; and aluminum and magnesium combined, 23%. The other 2% was used to make glass, ceramics, enamels, calcium cyanamide, welding rods, cement, uranium tetrafluoride, and nonferrous metal fluxes. Demand increased in the cement industry, which uses fluorspar to lower the burning temperature of limestone and other components, and in the refining of certain nonferrous metals.

During 1974, the steel industry reported the consumption of about 644,000 tons of met-spar, of which 66% was used in basic oxygen furnaces, 17% in open hearth furnaces, and 17% in electric furnaces. Another 27,000 tons was used for iron castings, and another estimated 45,000 tons was used to make HF for pickling of stainless steel, making the total consumption about 716,000 tons. Although steel-ingot output decreased, a 4% increase in fluorspar consumption was reported for 1974. The use of met-spar including briquets ranged from 3 to 11 pounds of fluorspar per ton of steel ingot and averaged about 9 pounds. No further notable decrease in the consumption of fluorspar in steel ingot production was anticipated for the near future. Fluorspar substitutes that have been tried either require at least 50% more of the substitute material than fluorspar to perform the same fluxing and cleaning actions, or contain deleterious elements which limit their use to specialty steels or certain types of furnaces. It was reported that the use of substitutes in the iron and steel industry had advanced further in Canada than in the United States. Substitute materials, such as colemanite, bauxite, ilmenite, olivine, limonite, and red mud or mixtures of them were being used to start a furnace batch or to mix with fluorspar to make briquets.

In 1973 and 1974, briquetting companies started a new trend that has increased the tonnage of briquets used and decreased the actual calcium fluoride consumption. Instead of changing to 100% substitutes, steel companies requested briquetting companies to mix acid-spar and met-spar with limestone, lime, and some of the acceptable fluxing substitutes thereby reducing the actual calcium fluoride content of some briquets to below 60%. Because some furnaces emit significant quantities of fluorine particulates or fluorine gas, it was anticipated that use of fluorspar substitutes will be encouraged to avoid environmental problems.

During 1974, the U.S. aluminum industry produced 4,903,000 tons of aluminum ingot. At the consumption rate of 128 pounds of acid-spar per ton of aluminum, the industry consumed 314,000 tons of acid-spar. The acid-spar was used to make HF, which in turn was used to make aluminum fluoride and sodium aluminum fluoride that were used to form the molten electrolyte in alumina-smelting potlines. A small amount of acid-spar was added directly to aluminum and magnesium reduction cells during operation, as shown in table 6.

Fluosilicic acid recovered as a byproduct from the phosphoric acid industry, was an additional source of fluorine used to make aluminum-cell electrolyte. In so doing, an additional 56,000 tons of acid-spar equivalent was used by the aluminum industry, thereby increasing the total acid-spar equivalent consumed by the aluminum industry to about 370,000 tons. When the fluosilicic acid supply was added, consumption increased to about 150 pounds of acid-spar equivalent, or 70 pounds of fluorine per ton of aluminum ingot.

The aluminum companies continued, at great expense, to improve techniques for recovery of fluorine. A few companies, by using Aluminum Company of America's

(Alcoa) dry scrubbing method, reported success in recycling up to 15% of the fluorine salt particulates. Spurred by government regulations and potential economic advantages, the aluminum companies also made progress in developing electrolyte recycling techniques to reduce consumption of primary fluoride salts. It was estimated that by 1977, if recycling continued to improve, consumption could be down to 120 pounds of acid-spar equivalent per ton of aluminum.

At yearend 1974 Alcoa's new aluminum-chloride electrolytic smelting plant at Palestine, Tex., went onstream. This plant, which used only a minor amount of fluoride to eliminate excess oxide, had an annual capacity of 15,000 tons of aluminum ingot. It was reported that this process, if successful, would not replace currently operating plants, but could in time be the selected process for new plants.

During 1974, about 824,000 tons of acid-spar, domestic and foreign, was used to make HF in nine HF plants in the United States. Most of the plants were located at coastal ports in Texas, Louisiana, New Jersey, and Delaware. All, including the inland plants, were accessible by water routes.[2] Imports of HF increased 3% as shown in table 10. The chemical and aluminum industries used about equal amounts of HF. Inorganic fluorides were manufactured from HF for use as insecticides, preservatives, antiseptics, catalysts, fluxes, in fire extinguishers, and for steel pickling. Elemental fluorine gas, which is derived from HF, is used to manufacture uranium hexafluoride from tetrafluoride, to produce sulfur hexafluoride, halogen fluorides, and emulsified perfluorochemicals. Organic fluorides were the volume leaders in the chemical industry using more than half of the HF produced. Organic fluorides were manufactured by reacting anhydrous acid (99.9% HF) with chloroform or carbon tetrachloride to produce a variety of chlorofluorocarbons. As chemically stable compounds, they performed outstandingly as refrigerants, aerosol propellants, solvents, resins, and elastomers. About 45% of the fluorocarbons produced were reportedly used as aerosol propellants which in 1974 made news in the trade magazines and newspapers.[3]

During the last week of October 1974, the National Resource Defense Council petitioned the Consumer Product Safety Commission to ban the use of fluorocarbon-aerosol propellants. These proposed restrictions and others were followed by a series of accusations and denials by scientists representing both sides of the argument as to whether chlorofluorocarbons containing F-11 and F-12 do or do not affect the ozone layer in the stratosphere. The hypothesis proposed is that in the atmosphere, ultraviolet radiation releases the chlorine from the fluorocarbon and the chlorine by means of a catalytic chain reaction reduces the density of the ozone layer which shields the earth from cancer-forming ultraviolet radiation. During the first week of December, Federal legislation to ban certain uses of fluorocarbons was proposed by a member of the House of Representatives. The bill also directed the Environmental Protection Agency to contract with the National Academy of Sciences to make a study of the situation and report back to Congress within 9 months.[4]

The proposed ban and the many reviews were soon followed by an announcement by the Federal Council for Science and Technology and the Council on Environmental Quality that the Interagency Task Force on Inadvertent Modification of the Stratosphere (IMOS) would investigate the possible relation of "Freons" (fluorochlorohydrocarbons) to future reduction in the ozone content of the atmosphere. By the end of 1974, sales of fluorcarbon aerosols were down, and fluoride orders by chemical manufacturers were being delayed.

The depressed market for fluorocarbons continued into 1975. It was estimated that it may be years before a scientific solution or explanation will be widely accepted, meanwhile, about 15% of the acid-spar market will be affected.

The nuclear power industry's demand for anhydrous hydrofluoric acid, fluorine gas and uranium oxide to produce uranium hexafluoride, can be estimated from information that was made available in 1974. The 1974 acid-spar demand was estimated at 15,000 tons for treatment of 12,000 tons of U_3O_8. Approximately 1.25 tons of acid-spar was required per ton of uranium oxide (U_3O_8) to make uranium hexafluoride (UF_6) from which the fissionable U_{235} isotope was subsequently separated by gaseous diffusion.

In the process, purified UO_3 derived from U_3O_8 was hydrofluorinated with anhydrous hydrofluoric acid at a rate of about 1 to ⅓ to produce uranium tetrafluoride (UF_4), which was then reacted with elemental fluorine gas to produce gaseous UF_6. Then the UF_6 was passed through the gaseous diffusion plant, and the UO_2 enriched in U_{235} was separated. Since the gaseous diffusion plants went into operation, UF_6 depleted of most of the U_{235} has been stockpiled. Fluorine losses in the process were negligible. The U.S. Energy Resource and Development Administration (ERDA) reported that it had in stock about 220,000 tons of fertile uranium, probably in UF_6 containing less than 2% U_{235}. This material contained about 70,000 tons of fluorine, equivalent to about 152,000 tons of acid-spar. This large stockpile, plus possible decreased consumption per nuclear-energy unit generated by uranium, beclouds long-range predictions of increased future fluorspar demand in fabrication of nuclear fuels.

Table 6.—U.S. reported consumption of fluorspar by end use and grade in 1974
(Short tons)

End use or product	Containing more than 97% calcium fluoride	Containing not more than 97% calcium fluoride	Total

Indiana	68,726
Michigan	48,670
New Jersey	39,951
Ohio	194,391
Oregon and Washington	1,274
Pennsylvania	191,708
Texas	318,070
West Virginia	55,224
Other States [1]	42,555
Total	1,524,532

[1] Includes Georgia, Maryland, North Carolina, Delaware, Mississippi, Iowa, Oklahoma, and Wisconsin.

STOCKS

U.S. producers reported a 58% increase to 13,700 tons in their stocks of finished fluorspar. Domestic-consumer stocks increased 31% to 430,600 tons. No sales were made by GSA from the Government stockpile, which remained at 1,302,000 tons, broken down as follows:

	Objective	Inventory	Excess
	(thousand short tons)		
Acid grade	--	890	890
Metallurgical grade	159	412	253
Total	159	1,302	1,143

At yearend, Mexican stocks were probably less than 100,000 tons. Worldwide inventories in major producing countries started to increase at yearend.

PRICES

Domestic fluorspar prices, f.o.b. Illinois, as reported in Engineering and Mining Journal (E/MJ), increased during the first three quarters of the year. The base price of dry acid-spar increased 9% from $78.50 to $85.50 per ton, and 70% effective CaF_2 met-spar pellets or briquets increased 7% from $65.50 to $70 per ton. According to E/MJ, acid-spar imported through Wilmington, Del., increased 5% to $102.50 per ton, but no fluorspar price increases were indicated at the Rio Grande Mexican border.

The world price of fluorspar was strongly influenced by Mexican producers because they supplied about one-third of the fluorspar sold on the open market; therefore, the price of fluorspar sold to U.S. consumers was indicative of the world price and price trends. At the beginning of the year, prices reported verbally for met-spar, on the Mexican side of the border, "mid-bridge," were $57 to $60 per ton. By yearend these prices ranged from $58.50 to $63 per ton. The largest Mexican producers, with long-term sales contracts, reported that the price of Mexican met-spar, 70% effective CaF_2 grade, had not changed notably in the past 2 years. During the first quarter, wet filter cake acid-spar prices, again verbally reported, ranged from $62.50 to $65 per ton f.o.b. "mid-bridge," about the same as quoted prices in E/MJ, but by yearend prices were reported to be $65 to $73.50 per ton.

Because of the energy crisis, freight costs increased notably during the year, and rates from Brownsville or Laredo, Tex., to the U.S. interior increased to $10 per ton. When the cost of the import duty, insurance, handling, and freight was added the price for Mexican met-spar delivered to the Ohio River industrial area was $80 to $83 per ton, and the price for wet acid-spar filter cake was $5 to $10 per ton more.

In general, price increase of about 5% on fluorspar shipped from European and African countries were the direct result of increased production and freight costs. Fluctuations in money exchange rates caused some price variations, particularly of spot sales. During the last quarter, when the industrial slump began to affect domestic demand, spot-sale prices fluctuated notably, inventories began to grow, and long-term contracts were hard to obtain. Also, freight rates were reduced to more competitive levels.

Table 8.—U.S. prices of fluorspar

	1973 [r]	1974
Domestic f.o.b. Illinois-Kentucky:		
Acid-grade concentrates, dry basis, 97% CaF_2:		
Carloads	$78.50–$87.00	$85.50–$103.00
Bags, extra	6.00	9.00
Pellets, 88% effective CaF_2 (briquets)	76.50	85.00
Pellets, 70% effective CaF_2 (briquets)	65.50	70.00
Ceramic-grade, 95% to 96% CaF_2	76.50–82.00	83.50–96.00
European: f.o.b. Wilmington/Philadelphia:		
Acid-grade, duty paid, dry basis	97.50	102.50
Mexican: f.o.b. Mexico:[1]		
Metallurgical-grade, 70% effective CaF_2:		
Border, all rail, f.o.b. cars	48.50	48.50
Tampico, Mex., f.o.b. vessel	50.00	50.00
Acid-grade, wet-filter-cake, 97% CaF_2:		
Eagle Pass, Tex., bulk	60.00–62.00	60.00–62.00

[r] Revised.

FOREIGN TRADE

A small quantity, approximately 6,000 tons, of fluorspar was exported, primarily to Canada. U.S. foreign trade, as in the past, continued to be with market-economy countries.

U.S. imports of fluorspar increased 10% to 1,336,000 tons equaling 94% of apparent consumption and 88% of reported consumption. Mexico continued to supply most of these imports, accounting for 80% of volume in 1974, with European and African countries supplying the remainder. Approximately 63% of U.S. imports were acid-spar, which increased 19% to 843,000 tons; the balance, mostly met-spar, was imported mainly from Mexico and decreased 3% in volume. An increasing amount of this met-spar was used to make briquets for use as a flux in steel furnaces. In addition to fluorspar, 32,000 tons of 70% hydrofluoric acid was imported, mainly from Canada, a 3% increase over 1973, and 20,000 tons of synthetic and natural cryolite was imported from 10 different countries.

Table 9.—U.S. exports of fluorspar

Year and country	Quantity (short tons)	Value

Italy	890	274
Japan	9,788	2,865
Netherlands	169	75
United Kingdom	20	8
Yugoslavia	135	42
Total [1]	19,896	6,689

[1] Only the material from Denmark is natural cryolite. All the rest is manufactured synthetic cryolite.

Note: About 1¼ tons of acid-spar are required to commercially produce 1 ton of cryolite (Na_3AlF_6); therefore, the 19,896 tons of cryolite imported in 1974 was equivalent to about 24,870 tons of acid-spar. Because only 20% of the imported cryolite is natural, the mineral cryolite is no longer considered to be a major source of fluorine and no longer justifies a separate section. The imported synthetic cryolite does represent a fluorine compound which could have been manufactured in the United States and would have consumed either fluorspar or fluosilicic acid to supply the fluorine.

WORLD REVIEW

Since 1971, when world production first peaked at over 5 million tons, world production and trade have remained steady. The top 10 fluorspar producing countries listed in table 15 accounted for about 82% of the world production. The largest importers were the United States, Japan, the U.S.S.R., Italy, and Canada, which accounted for about 90% of recorded exports. United States imports equalled about one-fourth of the world production, and about one-half of the world fluorspar trade. Approximately 31% of the world production was produced on the North American continent.

There were no major changes in market-economy country exports of fluorspar. Mexican exports increased 4% and continued to equal nearly 40% of world exports. French exports increased approximately 20% from 135,000 to 162,000 tons, and Italian exports decreased approximately 17% from 100,000 to 83,000 tons.

Fluorspar trade organizations or institutes existed throughout the world. The established organizations were: Fluorspar Producers' Development and Research Association in the United Kingdom, and the Thai Association of Fluorspar in Thailand. Newer organizations founded at yearend were the Bureau of International Technique du Spathfluor (BITS) headquartered at Brussels, Belgium, and the Instituto Mexicano De La Fluorita A.C. (IMF) headquartered in Mexico City.

In the fall of 1974, European and African fluorspar producers inaugurated BITS. Most of the major producers joined the institute, which reportedly was organized to encourage and promote the fluorspar industry, etc. Also in December 1974, the IMF was inaugurated. Mexican fluorspare producing companies represent a majority of the membership, and Mexican Government departments and agencies represent a minority. On January 24, 1975, a charter acceptable to the Mexican Government was drafted. The board of directors has 17 members; 11 represent the private fluorspar producers and the rest represent government departments or mining associations.

The U.S. Bureau of Mines was informed verbally by members of these organizations that the Institute's objectives are broad and include promoting the fluorspar industry and regulating export prices and export permits. To date, because of the plentiful supply of fluorspar on the world market, no fixed prices have been announced by the two organizations. However, IMF has already recommended Mexican export prices; it is apparent from present information that future prices of fluorspar imports into the United States may be regulated by the IMF.

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the countries listed, Bulgaria is also believed to have produced fluorspar, but production is not officially reported and available information is inadequate for the formulation of reliable output level estimates.

[2] An effort has been made to subdivide production of all countries by grade (acid, ceramic and/or metallurgical). Where the subdivision is available in official reports of the subject country, the data have been entered without qualifying notes; where a secondary source has been used to subdivide production by grade, the source of the basis for this subdivision has been identified by footnote. Where no basis for subdivision exists, the country entry has been identified with the notation ("grade unspecified").

[3] Information on grade obtained from: Bundesanstalt Für Bodenforschung Hannover and Deutsches Institut Für Wirtschaftsforschung Berlin. Untersuchungen über Angebot und Nachfrage Mineralischer Rohstoffe IV—Flusspat, March 1974, p. 39.

[4] Figures represent the difference between reported exports (divided by grade) and total production (reported with differentiation by grade).

[5] Figures reported represent total marketable product, which includes directly salable mine product and concentrate produced from ores that are not usable without beneficiation. Gross mine production of all grades reported in some sources totaled 694,000 tons in 1972, 623,000 tons in 1973 and 650,000 tons (estimated) in 1974. Much of this material requires beneficiation.

[6] Figures reported represent total officially recorded mine production of salable acid grade fluorspar from both fluorspar mines and lead-zinc-fluorspar mines plus estimate for the production of salable acid grade fluorspar obtained by beneficiating a portion of total officially recorded salable metallurgical-grade fluorspar output. Total officially recorded acid-grade fluorspar output was as follows in short tons: 1972—279,843; 1973—264,360; 1974—282,788. Estimated production of acid-grade fluorspar from beneficiated metallurgical grade fluorspar was as follows in short tons (with quantities of metallurgical-grade fluorspar recorded as being processed given in parentheses): 1972—64,832 (reported 162,080); 1973—49,927 (estimated 125,049); 1974—22,313 (estimated 56,013).

[7] Figures reported represent the difference resulting from the subtraction of that quantity of metallurgical-grade fluorspar consumed in beneficiation plants for the production of acid-grade fluorspar (see footnote 6) from total recorded metallurgical-grade fluorspar output from both fluorspar mines and lead-zinc-fluorspar mines. Recorded total mine output of metallurgical-grade fluorspar was as follows in short tons: 1972—261,694; 1973—235,049; 1974—166,013.

[8] Includes materials recovered from lead-zinc mine dumps.

[9] Although official sources recorded no production, there are indications that at least test lots were produced.

[10] Acid grade material reported from Thailand is an estimate of the quantity of beneficiated product resulting from processing of low-grade material officially reported; metallurgical-grade material is run-of-mine production reported under the term "high grade" in official sources. Recorded production of low-grade material follows in short tons: 1972—22,575; 1973—61,646; 1974—88,000 (estimated).

[e] Estimate. XX Not applicable.

[1] Compiled from official import data of listed countries of destination except where otherwise specified by footnote; figures in total receipts by listed countries column are simply summations of reported imports for all listed destinations, in contrast to figures in total recorded exports column which are either (1) actual reported exports of listed source countries, or (2) estimates of total exports. Differences between these two columns are attributed to (1) time lag between date of shipment and date of receipt, (2) concealment policies of some countries, and/or (3) reshipment of material by intermediate countries which may be credited as the origin in the trade returns of the final destination countries.

[2] Imports for year beginning July 1, 1978.

[3] No recorded production of fluorspar; exports are apparently derived from imported materials.

[4] Official import statistics show no receipts from this country, but do include a substantial quantity of material from undisclosed sources. Figure entered here represents reported export of source country to this destination. (An equal amount has been subtracted from the destination country's reported import from undisclosed sources.)

[5] Less than ½ unit.

[6] Data compiled from official import statistics of six nations and export statistics of nine significant producing nations, the latter to determine apparent imports for 20 other countries for which official fluorspar import figures are not available. Nations reporting imports and total recorded imports for each are as follows in short tons: Brazil 115; Denmark 2,282; Finland 4,639; India 746; Mexico 10; Spain 26. Nations for which apparent imports have been derived, and apparent imports for each are as follows in short tons: Argentina 2,967; Bulgaria 187; Czechoslovakia 2,585; East Germany 3,847; Greece 165; Guatemala 331; Hungary 1,725; Malaysia 432; Philippines 780; Portugal 1,049; Romania 1,248; Singapore 179; the Republic of South Africa 146; Sri Lanka 23; Switzerland 2,587; Taiwan 3,836; Thailand 424; Tunisia 77; Venezuela 3,212; South Vietnam 369.

[7] Figure compiled exclusively from official export statistics of the country of origin (see also footnote 6).

[8] Figure compiled from both the official import statistics of the countries of destination and official export statistics for the country of origin (see also footnote 6).

[9] Figure includes fluorspar as well as any nepheline and/or nepheline syenite exported.

[10] Figure includes fluorspar as well as any feldspar, nepheline and/or nepheline syenite exported.

[11] Estimate by the United Kingdom Institute of Geological Sciences.

Canada.—Nearly all of Canada's fluorspar production continued to come from the Burin Peninsula of Newfoundland, where the Newfoundland fluorspar works of Alcan Aluminum Ltd. (Alcan) operated two mines near the town of St. Lawrence. According to an official of Alcan, production was about 160,000 tons of heavy-media, met-spar of about 65% CaF_2, which was shipped to Arvida, Quebec, for processing into about 100,000 tons of acid-spar concentrate which was processed into aluminum smelter fluxes. But on table 13, preliminary estimates indicate Canadian production at 150,000 tons, which may have included some met-spar.

Although fluorspar imports reportedly decreased from 1973, Canada continued to import a little more fluorspar than was produced domestically. Most of the imported fluorspar was flotation concentrate containing more than 95% CaF_2. About 35,000 tons of met-spar gravel was imported for the steel industries. It was reported that many Canadian steel foundries were using ilmenite and olivine as a fluorspar substitute.

Of the total estimated fluorspar supply of about 317,000 tons, approximately 11% was used by the steel industry, 88% was used by the aluminum and chemical industries, and less than 1% was used by the glass, fiberglass, and enamel industries.

The only active fluorspar exploration reported was on the Burin Peninsula of Newfoundland, near where Alcan operates the Blue Beach and Tarefare mines, and one heavy-media plant. A new mine, Tarefare No. 2, which was to replace one of the mines that was nearly depleted, was still being developed and probably will not obtain full production until 1976.

Fluorspar mining in Newfoundland was started in 1933 by St. Lawrence Corp. In 1940, Newfoundland Fluorspar Co., a wholly-owned subsidiary of Alcan, opened the Director mine, 1.25 miles west of St. Lawrence. In 1962, St. Lawrence Corp. stopped all ore shipments; and in 1965, all local assets were sold to Newfoundland Fluorspar Co. In 1970, Newfoundland Fluorspar Co. was liquidated and became an operating division of Alcan. Since then, the mined and upgraded ore has been shipped to Arvida, Quebec, where it was processed in a flotation plant and used to make aluminum fluoride for Alcan's aluminum smelter. The ore occurs as veins ranging from 3 feet to 23 feet wide containing 60% to 95% CaF_2. The veins have been mined and developed from the surface to 1,400 feet deep. Mining has been plagued with large amounts of water and radon gas emission.[5]

e Estimate. p Preliminary.

China, People's Republic of.—China has been an important world producer of fluorspar for several years, and output in 1974 likely totalled 300,000 tons. A large surplus has been traditionally exported, mainly to Japan. Imports of Chinese fluorspar by Japan reached an alltime high of 197,300 tons in 1974, and imports by the U.S.S.R. in 1973 (the latest figure) was 54,000 tons. Poland was also importing as much as 13,000 tons for a single year. Most Chinese fluorspar appearing in the world markets was metallurgical grade, which was marketed predominantly to steel producers. Very high-grade lump fluorspar was recently offered in the U.S. market. Although still at low levels, fluorspar consumption in China has steadily increased. Possibly 100,000 tons of fluorspar was consumed in 1974; at least 50,000 tons by the steel industry and 50,000 tons by the aluminum and chemical industries.

Historically, the leading producing districts have been Wu-yi in Chekiang Province, Kaip'ing in Liaoning Province, and Lung-hua in Jehol Province. Fluorspar also has been mined in Shantung and Kwangtung Provinces. A new mine has come into prominence in recent years; namely the Taolin in Hunan Province, which also produces lead-zinc. A flotation plant at the mine has a reported capacity of about 80,000 tons annually. Another recently developed fluorspar operation is located in Pecheng, Fukien Province. There may not be many potential fluorspar deposits associated with lead and zinc since such deposits are uncommon according to present geological knowledge of the country.[6]

France.—Fluorspar production increased about 3% to approximately 300,000 tons, 63% of which was acid-spar averaging 98% CaF_2 and the remainder, met-spar averaging 80% CaF_2. Four companies produced 80% of this fluorspar which was recovered from 727,000 tons of washed ore. Ore assays have decreased every year from 63% CaF_2 in 1970, to 49% CaF_2 in 1974. Domestic fluorspar consumption decreased 7% to 231,000 tons of contained CaF_2. Approximately 100,000 tons of met-spar was consumed by the steel industry and 5,000 tons by the ceramic industry; the remainder, acid-spar, was used to produce aluminum fluoride, cryolite, and other fluorine compounds.[7]

Fluorspar exports, 69% to West Germany, increased 19% to 161,000 tons, of which 7 tons was met-spar and the remainder acid-spar. A small quantity, 5 tons, was imported, mostly met-spar. Two of the larger producers were Péchiney Ugine Kuhlmann of Haute Laire and Ste. de Concentration des Mineraux Fluores, in the Pyrenes.

Italy.—Italian production, trade, and consumption for 1973 and 1974 were as follows, in thousand short tons:

	Production	Exports	Imports	Consumption
1973	260	100	41	201
1974	275	83	74	266
Change	+6%	−17%	+80%	+32%

Most of the 1974 exported material was acid-spar and about half of it went to the United States. About 70% of the imported material was met-spar, from Tunisia, France, and Mexico.

About 60% of Italy's production continued to come from the island of Sardinia. Fluorsarda, a subsidiary of the Sardinian Mining Agency began a 3-year exploration program in the Sarrabus-Serrei and Sarcindano areas.

Ente Gestione Aziende Mineraria S.p.A. (EGAM), the Italian Government holding company, in fulfilling its commitment of a national mining policy, expanded into the nonmetallic field especially in Sardinia. EGAM prefers to operate its own mines; but where this is not feasible they acquire a minority participation in local companies. They have also made proposals to enter into long-term purchase agreements and joint undertakings with producing countries to assure Italy adequate supplies of raw materials.

The major fluorspar mining companies in Italy were as follows: Soc. Mineraria Silius S.p.A., (C.E. Giulini Gp) Cagliari Province, Soc. Montedison, Bergamo, Brescia and Trento Provinces, Montecatini-Edison S.p.A., Northern Italy, Soc. Pertusola, Cagliari Province, Soc. Mineraria Prealpina, Bolzano Province, Fluorsid S.p.A. (C.E. Giulini Gp), Assemini, Cagliari Province and Southland Mining Ltd. (Soc. Rich. Colt. Minerarie-Pianciano) Rome Province.

Mexico.—Mexico maintained its position as the leading world producer and exporter of fluorspar, and the foremost supplier to the United States. The country's 1974 production, about one-fourth the world's production, increased 2% to 1,226,000 tons which was still below the 1971 peak of 1,302,000 tons. The majority of the larger companies continued in full production in 1974. Seven major mines have the capacity to produce about 1 million tons, or over 90% of the total.

Cía. Minera Las Cuevas, S.A., which was 51% owned by Mexican interests and 49% by Empresa Fluorspar Mine Ltd., a Noranda Mines Ltd. of Canada affiliate, was still the largest fluorspar mine in the world. The complex is located about 60 kilometers (37 miles) east of San Luis Potosí near the town of Zaragoza. According to Noranda's 1974 annual report, this mine produced 375,000 tons. Approximately 240,000 tons was gravel metspar and the rest was used to make about 80,000 tons of acid-spar. Plans were announced to increase the acid-spar capacity to 100,000 tons annually. Most of the company's fluorspar was shipped by rail to Texas, but some was shipped to Tampico, Vera Cruz, for exporting.

Table 16.—Selected fluorspar mining companies in Mexico and their approximate shipping capacity in 1974
(Thousand short tons)

Company	Location	Capacity
Cía. Minera Las Cuevas, S.A	Zaragoza, San Luis Potosí	350
Minera Frisco, S.A	Parral, Chihuahua	210
Fluorita de Mexico, S.A	Muzquiz, Coahuila	130

Association of Small Miners	Rio Verde, San Luis Potosí	60
Fluoros de Hidalgo, S.A	Ixmiquilpan, Hidalgo	25
Reynolds Mining Corp	Piedras Negras, Coahuila, Eagle Pass, Tex	90
Total		1,315

The combined production capacity of the 12 companies listed in table 16 totals about 1,315,000 tons of fluorspar. About 63% of the capacity is in acid-spar. Normally, they operate at about 95% of capacity.

Fluorspar continued to be Mexico's single most important mineral export, and 1974 exports increased 4% to 1,164,600 tons. This was about 95% of Mexico's production. Exports to the United States increased 19% in volume, to 1,064,000 tons, and supplied 80% of U.S. imports or 75% of U.S. apparent demand. This expansion was due entirely to increased exports of acid-spar which increased 50% in volume, to 603,000 tons, and 71% in customs-declared value. Acid-spar accounted for 57% of 1974 fluorspar exports to the United States. Export of met-spar, the only other grade of fluorspar shipped to the United States, decreased 6% in volume to 461,000 tons, and decreased 9% in customs-declared value.

Average reported customs-declared value f.o.b. foreign port was $31 per ton for met-spar, and $51 per ton for acid-spar. Average prices of fluorspar on the Mexican side of the border were held fairly steady by Mexican producers at approximately $60 per ton for met-spar and $73.50 per ton for wet acid-spar filter cake. Yearend prices on spot sales, which extended into 1975, did not fluctuate more than 3%.

Internal fluorspar consumption remained steady at an estimated 60,000 tons. The steel industry remained the largest consumer, but the combined consumption by the chemical and aluminum industries was nearly equivalent. No significant change occurred in inventories. All production was apparently consumed or exported.

In August, in response to rising production and freight costs, the National Federation of Association of Small-Scale Miners and the National Association of Small Fluorspar Producers met under the auspices of the National Mining Development Commission of the Mexican Government to force a 60% increase in the price of fluorspar. The attempt was unsuccessful, owing to world market conditions and the reluctance of the larger producers to go along with the increase.

Production costs increased during 1974 because of a 22% wage increase granted all salaried Mexicans in September, and small incremental wage increases owing to a series of labor strikes. Consequently, some increase in true export prices may be anticipated for 1975.

Currently, there are two HF acid plants in Mexico, Industrias Químicas de Mexico, S.A. (Fluor-Mex) at San Luis Potosí and Quimobasicos, S.A. (Cydsa Group) at Monterrey, Nuevo Leon, which normally consume about 20,000 and 7,000 tons per year of acid-spar respectively. The combined output of these two plants has averaged about 12,000 tons of HF annually. Progress continued on construction of the HF plant being built near Matamoros by Química Fluor, S.A. de C.V. This plant has a rated input capacity of about 155,000 tons of acid-spar and an anticipated output of about 70,000 tons of HF annually. The plant is jointly owned by the Mexican Government (Comisíon de Fomento Minero), E. I. du Pont de Nemours & Co., Minera Frisco, S.A., and Banco de Commercio. Du Pont is the plant builder and operator, and most of the output is scheduled for U.S. consumption. Completion is expected by mid-1975. When in full operation in 1976, Mexican internal consumption of acid-spar reportedly will increase fourfold.

Mongolia.—Mongolia continued as a significant world producer of fluorspar with an estimated production of 265,000 tons for both 1973 and 1974. Nearly all of this material was shipped to the U.S.S.R. Soviet aid to the Berhin fluorite mine was doubled.

South Africa, Republic of.—Fluorspar production showed a modest reduction from 1973 of about 1% to 229,200 tons. Acid-spar production was about 13 times greater than all other grades of fluorspar. Reportedly, acid-spar production greatly exceeded export and local sales causing accumulation of excessive acid-spar stocks. Met-spar gravel production decreased over 100%, and sales were made mainly to the local iron and steel industry. About 147,600 tons of all grades was exported and 20,100 tons was used internally leaving about 61,500 tons of producers' stockpiles. Since 1972, total production has decreased 1%; acid-spar production has increased 35%; and met-spar and ceramic-spar combined production have decreased 79%, indicating drastic changes in production capabilities and market outlook.

At the Buffalo fluorspar mine of General Mining and Finance Corp., Ltd., plant expansion continued to increase the company's output of acid-spar, and the Monico Fluorspar Co. of United Steel Corp. continued expansion programs. Other companies mining fluorspar in the Republic of South Africa included Vergenoeg Mining Co., Montrose Exploration Co., Bethlehem Steel Corp. and Phelps Dodge Co.

It was evident from the recent years of notable increases in acid-spar production, that the future of the industry in South Africa depended on the marketability of flotation concentrates. It was questionable, and still is, whether the world market could absorb a predicted production increase of 300,000 tons from South Africa, 200,000 tons from Europe, Morocco, and Kenya, and another 100,000 tons from Mexico by yearend 1975. Therefore, it was suggested that South African companies may be planning to briquet their oversupply of flotation concentrates or ship them to briquetting plants in iron- and steel-producing countries. At the Buffalo mine, a briquetting unit was reported to be under construction.

Fluorspar reserves of the Republic of South Africa and the Territory of South-West Africa were reported to be equivalent to about 35 million tons of 35% CaF_2, but their resources are much larger. Although the largest deposits are low grade, ranging from 15% to 20% CaF_2, they are minable by open pit methods and are economically exploitable in today's market. It was predicted that South Africa and South-West Africa will have the capacity to produce 455,000 tons annually by 1976.

The Maydon Wolf No. 5 storage and shipping facilities located at Durham, South Africa, were scheduled for completion by yearend 1975. Scheduled loading capacity was 14,000 tons per day, and by 1976 they anticipated exporting 300,000 tons of acid-spar and minor amounts of met-spar. These new port facilities were being constructed by Rennees Consolidated Ltd. Fluorspar exports that formerly were shipped from Lourenço Marques, Mozambique, will probably, in the future, be shipped from Durham.

Spain.—Production decreased about 2% to 415,000 tons, mainly due to the adjustments of the metallurgical-grade quantities which were not sold as a finished product. Spain's production did not show any increase from 1972 through 1974, although production capacity was increased.

In reports by the U.S. Embassy in Madrid, the production of fluorspar as metallurgical-grade material also included the production of mine-run ore containing 59% CaF_2, which was not a marketable finished product. This lower grade mine-run ore was probably fed into an upgrading plant to produce satisfactory 70% effective metallurgical-grade fluorspar or to a flotation plant to produce acid-spar. To keep Spain's reported figures comparable with those reported for the rest of the world for 1973 and 1974, Spain's met-spar production figures were adjusted as shown in table 13. Northern Spain, which contains most of the country's reserves, continued to annually produce the largest tonnage of fluorspar.

Fluoruros, S.A. completed installation of a briquetting circuit at their year-old Espasa fluorspar flotation plant located in Asturias. Plans were announced to increase Spain's production of aluminum, which indicates a future rise in domestic acid-spar consumption. Other companies producing fluorspar were: Minerales y Productos Derivados, S.A. in Almeria, Arlos, S.A. in Aviles, and Fluoritas Asturiannas, S.A. in Caravia.

Thailand.—During 1974, about 430,000 tons was produced representing a 3% increase over 1973 production. This represented a 54% increase to 59,500 tons of acid-spar, and a 2% decrease to 370,500 tons of met-spar. About 188,000 tons of met-spar was exported to Japan; the rest was shipped to the U.S.S.R., Singapore, Australia, Taiwan, India, the Philippines and South Vietnam. Less than 1,000 tons of met-spar was used internally in the steel industry.

Thai Fluorite Processing Co. Ltd.'s acid-spar-producing plant, located in Petchaburi Province and jointly owned by Kaiser Cement Co. (60%) and Jalaprathan Cement Co. (40%), continued in full operation during the year. This was the only fluorspar froth flotation plant in Southeast Asia. During the year the company abandoned its mining operations and adopted a policy of supplying the plant with custom ore. All acid-spar was sold to Ataka Trading Co. of Japan, and most of it was shipped to Japan.

Although Japan was trying to diversify its sources of fluorspar, the country still imported over 65% of its demand from Thailand. Universal Mining Co. Ltd., which was controlled by Japanese interests, continued to operate its heavy-media separating plant in the Ban Hong district near Chiengmai, Lamphun Province.

About 155 fluorite deposits have been identified in Thailand. During 1974, an average of 76 deposits were worked and regularly employed about 6,600 people. During the last 4 months, employment dropped until there were only about 5,000 people employed in mining at yearend. Thailand was among the top five countries in world production and reserves. Thailand's reserves were estimated to be about 30 million tons of fluorspar containing about 35% CaF_2, but it was believed that only half could be classified as economically minable. Potential resources are large.

The domestic price of met-spar averaged $38.35 per ton on the Bangkok market for the first 6 months, but by yearend increased to about $46 per ton. The export price, f.o.b. port of Bangkok, was usually $1 to $3 more per ton, and this price also increased toward the end of the year. At the beginning of the year, acid-spar was quoted at $65 per ton, but by yearend the price was up about 15%, f.o.b. port of Bangkok. The rising value of fluorspar at yearend reflected increased costs of wages and fuel.

No further activity was reported on the January proposal by a Thai-Australian venture to build a $2 million flotation plant in the Cha-am area to produce 150,000 tons annually of chemical-grade fluorspar.

Effective July 10, 1974, the Royal Thai Government Customs Department reduced import tariffs on natural cryolite, chiolite, fluorspar, and on synthetic fluorine salts and fluorosilicates from 30% to 10% ad valorem.[8]

United Kingdom.—Estimated production was 187,000 tons, about the same as for 1973. Acid-grade production was down, but metallurgical-grade production was up. Exports were down a little and mining operations continued at about 75% of capacity. Continued disruptions in domestic and European markets, due to worldwide industrial recession, made a soft market. A recent evaluation of the United Kingdom fluorspar reserves resulted in an estimate of 24 million tons containing the equivalent of 35% CaF_2. Of this total, about one-fifth is considered as proven ore and the rest is considered as indicated and inferred reserves. The two major fluorspar mining companies were Laporte Industries Ltd., and Industrie des Metaux (G.E. Giulini Gp).

TECHNOLOGY

Environmental restrictions or controls have required technological changes in the fluorspar industry; however, it was acknowledged that meeting the various restrictions required additional investment and caused significant increases in cost of production, which have resulted in loss of capacity and even shutdowns of mines or mills. In Illinois and Colorado, the disposal of mill tailings created a problem because, even after impounding and clarification, the liquid mill effluents contained traces of chemicals that were considered deleterious and in violation of some environmental standards. The lack of uniformity in the standards set by different States and the Federal Environmental Protection Agency hindered industry in selection of proper technology and in future planning. Uniform controls are needed to prevent disruption of the industry as well as a loss of reserves.

To date, environmental problems have mainly affected users of fluorine salts, such as the chemical and aluminum industries. Restrictions already have been established on the permissible quantity of fluorine gases emitted from aluminum potlines. Most of the major aluminum companies have complied or were in the process of complying.

Throughout the country, about 2 parts per million fluorine has been the standard for fluoridation of public drinking water. Some natural streams analyzed double this amount. Some state regulatory departments were careful not to lower their control standards below the normal amounts found in nature.

The Federal Bureau of Mines Albany, Oreg., Metallurgy Research Center continued research on fluorine recovery technology. A program to study the recovery of fluosilicic as a byproduct during the production of phosphoric acid was in a semicontinuous miniplant stage. The acid can be converted to synthetic fluorspar, aluminum fluoride, or cryolite. In a concurrent investigation, recovery of fluorine from low-grade fluoride ores was being studied.

Gallium

By E. Chin [1]

Domestic production of gallium in 1974 declined substantially from the 1973 output. Although data on world production of gallium metal are not available, estimated world output in 1974 was about 10,000 kilograms. Most of the consumption of gallium continued to be in the production of intermetallic compounds such as gallium arsenide and gallium phosphide, which were used to manufacture light-emitting diodes for optoelectronic visual display panels.

Table 1.—Salient gallium statistics
(Kilograms)

	1971	1972	1973	1974
United States:				
Production -----	W	W	W	W
Imports for consumption -	2,671	6,066	11,124	6,536
Consumption ---	2,289	5,076	8,496	6,941
Price per kilogram dollars --	750	750	750	750

W Withheld to avoid disclosing individual company confidential data.

DOMESTIC PRODUCTION

Production of gallium metal in 1974 was by three companies. Gallium metal was produced as a byproduct of alumina production by the Aluminum Co. of America (Alcoa) at its Bauxite, Ark., plant. Gallium metal, oxide, and trichloride were produced by Eagle-Picher Industries, Inc., at its Quapaw, Okla., facility. Canyonlands 21st Century Corp. produced some gallium metal at its Blanding, Utah, plant. In addition, gallium metal and compounds derived primarily from imported material were supplied by Atomergic Chemetals Co., Cominco American, Inc., European Electronics, Inc., B. Freudenberg, Inc., Indium Corp. of America, and Kawecki Berylco Industries, Inc.

Alcoa completed construction of its new gallium extraction and refining plant at Bauxite, Ark., in mid-1974. The $1 million facility uses Alcoa's proprietary gallium production technology and reportedly triples the company's production capacity for gallium metal.

Scientific Gas Products, Inc., Edison, N.J., developed a new process for recovering high-purity gallium from gallium arsenide and gallium phosphide scrap material. The recovered gallium is reportedly of 99.999% purity. The company established facilities to process scrap material, either on a fee basis or by purchasing the scrap and reselling the pure gallium.

CONSUMPTION

The largest use for gallium was in optoelectronic applications, principally in the form of gallium arsenide and gallium phosphide, which are used in light-emitting diodes (LED's). LED's emit infrared light, have a long service life, and consume little electrical power, and were increasingly used in visual display systems in calculators, digital clocks and watches, medical instrumentation, multiple warning lights, and instrumentation for aircraft and automotive dash panels. Gallium arsenide continued to have extensive application in the field of microwave devices, where it operates efficiently beyond the cutoff frequencies of silicon-base diodes. The manganese-doped magnesium-gallium spinel ($MgGa_2O_4$:Mn) is a green phosphor used in ultraviolet excitation and was used in fluorescent lamps in Xerox copying machines. Gallium compounds were also used in semiconductor applications for microswitching devices and in laser applications. The intermetallic compounds, vanadium-gallium and columbium-gallium, were used as superconductors with a high transition temperature and a high critical field.

---

[1] Physical scientist, Division of Nonferrous Metals.

Approximately 97% of the gallium consumed in 1974 was for electronic applications. Major consuming firms included Bell & Howell Co., Bell Telephone Laboratories, Inc., Hewlett-Packard Laboratories, Laser/Diode Laboratories, Inc., Litronix Inc., Monsanto Co. (Monsanto), Motorola, Inc., Opcoa, Inc., RCA Corp., Texas Instruments, Inc., Texas Materials Laboratories, Inc., and Western Electric Co., Inc.

Arthur D. Little, Inc., of Cambridge, Mass., announced the formation of a new enterprise to be known as Intermat Corporation. The firm will design, manufacture, and sell high-pressure and high-yield furnace systems to produce commercial quantities of electronic materials such as gallium arsenide and gallium phosphide. A new company, Compound Semiconductor Materials, Inc., Stephenville, Tex., was formed to produce large quantities of single-layer, liquid-phase epitaxial gallium phosphide wafers, which are green-emitting materials. Other products will include yellow wafers and materials for high-efficiency infrared emitters. Another new company, Optical Diodes, Inc., manufactured optoelectronic components and subsystems. Some of the products offered by the firm include gallium arsenide, gallium arsenide-phosphide, and gallium phosphide devices; displays for calculators, clocks, and wristwatches; and optoelectronic instrumentation and systems.

STOCKS

Consumer stocks of gallium metal, low- and high-purity grades, totaled 560,711 grams as of December 31, 1974. Stocks a year earlier were 1,091,203 grams. Gallium metal stocks held by producers and suppliers were as follows:

Yearend—	*Grams*
1971	402,875
1972	1,005,945
1973	948,947
1974	4,037,917

Table 3.—Stocks, receipts, and consumption of gallium
(Grams)

Purity	Beginning stocks [1]	Receipts	Consumption	Ending stocks [1]
1973:				
97.0%–99.9%	14,854	9,400	10,342	13,912
99.99%	3,808	8,670	10,759	1,719
99.999%	9,200	42,275	46,422	5,053

Total	1,091,203	6,410,976	6,941,468	560,711

p Preliminary.
[1] Consumers only.

PRICES

As the bulk of the demand for gallium is for high-purity metal (99.9999%+), published price quotations for lower grade materials were eliminated in mid-1973. Subsequently, only dealers' and producers' quotes for high-grade gallium were published. Throughout the year, the dealers' and producers' published price quotations for gallium, in dollars per gram, were $0.70 and $0.80, respectively.

FOREIGN TRADE

Exports of gallium are not reported separately and are included in the category base metals and alloys, not elsewhere classified, wrought or unwrought, waste and scrap.

Total U.S. imports of gallium in 1974 were 6,536 kilograms, valued at $4,106,742, compared with 11,124 kilograms, valued at $6,073,479, in 1973. Shipments from the Netherlands and Switzerland accounted for 98% of the total U.S. imports of gallium. The unit value of gallium imports ranged from $614 per kilogram for material from the Netherlands to $3,018 per kilogram for gallium imports from Japan. The average unit value of all gallium imports in 1974 was $628 per kilogram.

Table 4.—U.S. imports for consumption of gallium (unwrought, waste and scrap), by country

Country	1973		1974	
	Kilograms	Value	Kilograms	Value
Belgium-Luxembourg	--	--	2	$1,502
Canada	2,133	$1,102,332	59	38,070
China, People's Republic of	4	2,652	--	--

(1) Less than ½ unit.

WORLD REVIEW

Data on world production of gallium are not available. However, the estimated world output was around 10,000 kilograms in 1974. Swiss Aluminium Ltd. was the world's largest producer of refined gallium.

World producers of gallium, by company, location, and raw materials source, follow:

Country	Company	Location	Source
Canada	Cominco, Ltd	Trail, British Columbia	Zinc ore.
China, People's Republic of	NA	NA	NA.
Czechoslovakia	NA	NA	NA.
France	Alusuisse France S.A	Marseilles	Bauxite.

TECHNOLOGY

The domestic gallium resource position was reviewed in a Geological Survey publication.[2] Gallium is so dispersed in nature that no deposits are known that could be exploited solely for its recovery.

A review of gallium discussed production, international trade, uses, and prices.[3] Future trends in supply, demand, and prices were included in the survey.

An extensive review of the literature concerning gallium was published.[4] The bulletin is an index to published articles, and the entries are cataloged as to geochemistry, purification, properties, composition, and analysis.

The Fifth International Symposium on Gallium Arsenide and Related Compounds was held in Deauville, France, September 24–26, 1974. Papers were presented on material properties, microwave and optical devices, and device technologies.

Reports on the growth of crystals for electronic uses were published.[5] Crystals of significant commercial and scientific interest were discussed, and the reasons for using specific growth techniques for particular crystals were presented.

A report on the status of LED technology was published.[6] The article reviewed the different types and colors of LED's that are commercially available or can be expected to become available in the near future.

Information concerning research on gallium arsenide for use in laser applications were published.[7] The long-range goal is to provide arrays of circuit elements capable of combining various discrete operations on guided light beams into sophisticated signal processing and communication devices and systems.

Gem Stones

Robert G. Clarke[1]

The production value of gem stones and mineral specimens in the United States during 1974 was estimated to be $4.6 million, an increase of 70% over that of 1973. Most of the value was contributed by the few companies which operated deposits for emerald, jade, opal, sapphire, and turquoise. Amateur collectors were important even though their total contribution was surpassed by the commercial operators. The commercial operators sold mainly to wholesale or retail outlets and occasionally to jewelry manufacturers.

DOMESTIC PRODUCTION

Gem stone production was estimated to be $1,000 or more for each of 39 States. The following States accounted for 70% of the total production value in thousands: Arizona, $1,500; Oregon, $500; Montana, $400; Nevada, $400; California, $220; and New Mexico, $200.

Gem stones are considered as one of the reliable items of value sought by people as a hedge against inflation. Added to this demand, the recent tremendous increase in American Indian jewelry has stimulated the turquoise mining industry to new records in value of output.

The Fairburn agate received its name from the town in which it was found first, Fairburn, S. Dak. Fairburns are beautiful agates noted for many fine lines in the pattern and brilliant natural colors. Because of the sharp contrasts of red, white, yellow, and black bands, they are often considered the world's most beautiful agates. Good ones sell for $5 to $100 per pound. Two articles described the collecting areas.[2]

Cape May "diamonds" are little quartz pebbles washed onto New Jersey beaches.[3] These are sold in most Cape May souvenir shops. In addition to beachcombing for the "diamond" quartz pebbles, collectors also gather pebbles of citrine, rose quartz, amethyst, smoky quartz, unakite, jasper, basanite, ilmenite, zircon, and various fossils of shellfish.

Several good quality diamonds, up to 2 carats in weight, were found at the Crater of Diamonds State Park in Arkansas, according to reports from park authorities.

Some of the world's finest sparkling quartz crystals are found in northern and western Arkansas where the collecting localities are numbered by the dozens.[4] Amateurs are permitted to collect at the commercial mine described. The record clear crystal from the operation measured 57 inches in length and 37 inches in width.

Descriptions of field trips, events, and mineral and gem stone finds were reported regularly in the following publications: Gems and Minerals, Lapidary Journal, Mineralogical Record, and Rocks and Minerals.

The quantity and value of emerald, jade, sapphire and tourmaline produced domestically were withheld to maintain confidentiality. About 9 tons of rough opal was produced and was valued at $68,000. The production of turquoise of all grades and qualities was nearly 160 tons valued at $2.0 million. Producers of gem stones in the United States, by principal gem stone reported, were as follows:

Blue Jim mine, Lander County, Nev., operated by James Elquist, Box 255, Battle Mountain, Nev. 89820.

Cortez Canyon mine, Lander County, Nev., operated by Nevada King Turquoise Co., P.O. Box 21, Searchlight, Nev. 89046.

Duval mine, Mohave County, Ariz., turquoise operations by L. W. Hardy Co., Inc., 3809 E. Highway 66, Kingman, Ariz. 86401.

Pinto Valley mine, Gila County, Ariz., operated by L. W. Hardy Co., Inc., 3809 E. Highway 66, Kingman, Ariz. 86401.

Red Mountain Turquoise mine, Lander County, Nev., operated by Donald B. Potts, Box 629, Tonopah, Nev. 89049.

Shoshone mine, Lander County, Nev., operated by Lombardo Turquoise Milling and Mining Co., Box 148, Austin, Nev. 89310.

Tina Gem mine, Lander County, Nev., operated by Richard G. Bonner, Box 948, Fallon, Nev. 89406.

Villa Grove Turquoise mine, Saguache County, Colo., operated by Clayton C. Musick, Box 101, Villa Grove, Colo. 81155.

CONSUMPTION

Domestic gem stone output went to amateur and commercial rock, mineral, and gem stone collections, objects of art, and jewelry. Apparent consumption of gem stones (domestic production plus imports, minus exports and reexports) was $401 million, about 5% less than that of 1973.

PRICES

Typical costs to a retail jeweler for a 2-week period in December 1974 for representative gem stones, based on a survey of dealers in all parts of the United States, were as follows:[5]

---

[5] Jewelers' Circular-Keystone. JC-K's Colored Stone Price Index. V. 145, No. 5, February 1975, p. 51.

Gem stone	Carat weight	Median price per carat	Price range per carat
Amethyst	10	$12	$8–$20
Aquamarine	8	95	60–200
Black opal	3	300	200–1,500
Cat's-eye	10	1,000	600–5,000
Citrine	10	6.50	4–20
Emerald	1	1,100	500–7,000
Green garnet	1	275	150–400
Man's sky blue star	10	200	80–1,000
Peridot	15	40	25–60
Ruby	2	800	350–15,000
Sapphire	2	500	250–2,200
Tanzanite	5	220	200–500
Tourmaline	10	35	20–75
White/opal fiery	5	80	35–100

Turquoise prices, wholesale, per pound, Kingman, Ariz., were as follows:

Natural turquoise

	Low-grade	Medium-grade	High-grade
Kingman mine	$80	$100–125	$200–250
Castle Dome mine	80	100–125	150–200

Treated, cutting-grade turquoise

Grade 1—Blue	$60
Grade 1—Blue Green	40
Grade 1—Green	30

Treated, tumbled-polished turquoise

¼-inch = small; ¼-inch-½-inch = medium; ½-inch and up = large. The tumbled-polished turquoise is the same price regardless of size.

Grade 1—Blue	$60-$80
Grade 1—Blue Green	20-40
Grade 1—Green	20-40

Stabilized turquoise

Grade 1	$100
Grade 2	80
Grade 3	60

No survey was made of diamond prices. However, diamond price trends indicated that a 25% increase occurred in the higher range and that the lower range was unchanged.

FOREIGN TRADE

Exports of all gem materials amounted to $320.7 million, and reexports to $165.3 million. Diamond accounted for 95% of the value of exports and 92% of the value of reexports. Exports of diamond in total were 285,136 carats valued at $304.6 million. Of this total, diamond cut but unset, suitable for gem stones, not over 0.5 carat, was 50,340 carats valued at $18.1 million; and cut but unset, over 0.5 carat, was 234,796 carats valued at $286.5 million.

Reexports of diamond amounted to 1,176,132 carats, valued at $151.8 million, in categories as follows: Rough or uncut, suitable for gem stones, not classified by weight, 1,059,089 carats valued at $92.7 million; cut but unset, not over 0.5 carat, 56,686 carats valued at $13.3 million; cut but unset, over 0.5 carat, 60,357 carats, valued at $45.9 million.

The seven leading recipients of diamond exports accounted for 92% of the carats and 95% of the value and were as follows: Hong Kong, 80,627 carats valued at $87.8 million; Switzerland, 75,933 carats, at $63.9 million; the Netherlands, 36,107 carats, at $58.2 million; Japan, 37,247 carats, at $30.6 million; Belgium, 20,170 carats, at $28.6 million; West Germany, 7,822 carats, $10.9 million; and France, 4,968 carats, at $10.2 million. The six leading recipients of diamond reexports accounted for 93% of the carats and 90% of the value and were as follows: Israel, 437,476 carats valued at $41.3 million; Belgium, 383,943 carats, $33.1 million; the Netherlands, 197,919 carats, $31.0 million; Switzerland, 54,924 carats, $20.8 million; Japan, 8,812 carats, $5.3 million; Hong Kong, 12,454 carats, $5.0 million.

Exports of all other gem materials amounted to $16.0 million. Of this total, pearls, natural and cultured, not set or strung, were valued at $0.8 million. Natural precious and semiprecious stones, unset, were valued at $13.3 million; and synthetic or reconstructed stones, unset, were valued at $2.0 million. Reexports of all other gem materials amounted to $13.5 million. Reexports of pearls amounted to $0.9 million; of natural precious and semiprecious stones, unset, to $12.5 million; and of synthetic or reconstructed stones, unset, to $0.1 million.

Imports of gem materials decreased 6% in value from those of 1973. Diamond accounted for 86% of the total value of gem material imports.

Although rough and uncut diamond imports were reported from 28 countries, over 99% in value were from 10 countries as follows: The United Kingdom, 911,165 carats, $211.8 million; the Republic of South Africa, 389,222 carats, $69.0 million; Sierra Leone, 453,084 carats, $57.6 million; the Netherlands, 51,101 carats, $19.2 million; Belgium-Luxembourg, 43,260 carats, $14.8 million; Liberia, 5,724 carats, $8.7 million; Venezuela, 382,738 carats, $8.2 million; Israel, 36,878 carats, $8.1 million; Central African Republic, 131,912 carats, $6.8 million; and France, 30,501 carats, $5.7 million. Cut but unset diamonds, not over ½ carat were imported from 30 countries; however, the imports of this category from 8 countries amounted to 99% of its total value as follows: Belgium-Luxembourg, 838,552 carats, $119.7 million; Israel, 710,386 carats, $109.3 million; India, 219,250 carats, $26.5 million; the Republic of South Africa, 12,956 carats, $3.8 million; the Netherlands, 28,183 carats, $3.6 million; the U.S.S.R., 13,161 carats, $2.6 million; the United Kingdom, 16,967 carats, $2.3 million; and, France, 19,557 carats, $2.1 million.

For diamond cut and unset, over 0.5 carat, 98% in value came from the following six countries: Belgium-Luxembourg, 114,815 carats, $43.2 million; Israel, 63,234 carats, $19.6 million; the Republic of South Africa, 9,837 carats, $6.0 million; the Netherlands, 3,714 carats, $1.4 million; the U.S.S.R., 1,964 carats, $1.0 million; and, the United Kingdom, 1,742 carats, $0.9 million.

Imports of emeralds increased 16% in quantity and 4% in value. Imports of rubies and sapphires increased 8% in value. Natural pearls and parts increased 20% in value but cultured pearls decreased 4% in value. Imitation pearls decreased 19% in value. Other precious and semiprecious stones, rough and uncut, decreased 21% in value. Other precious and semiprecious stones, cut but unset, increased 16% in value and others, not in these categories, increased 21% in value. Synthetic gem stones, cut but unset, decreased 37% in value and imitation gem stones increased 29% in value.

WORLD REVIEW

Australia.—Descriptions of the two areas in Australia, where most of the world's sapphires are produced, was provided in a recent issue of the Lapidary Journal.[6] The Swanbrook mine, near Inverel, several hundred miles north of Sydney, New South Wales, is a strip mining operation of Dominion Mining N.L. and is one of the largest of about 50 mines in the area. Each truckload of gravel mined contains about 100 grams (2 ounces) of sapphire of which about 10% is gem quality and sold by the carat. The rest of the sapphires are sold by the kilogram to collectors. Mechanical separation by screens and sieves is done first, followed by hand-sorting to pick out the materials which cannot be separated mechanically. The mine is in a cultivated area and all land is restored to its original condition. The Queensland sapphire fields are in the vicinity of the settlement of Anakie, about 200 miles west of Rockhampton. Individual miners are allotted mining areas 66 by 66 feet. The sapphire-bearing gravel is generally not more than 3 feet deep and mining is done by hand. If water is available, the gravel is washed over a screen, but dry sorting is also practiced in this arid area of Australia.

Production of opal in Australia probably accounts for 98% of the world's supply. Several well-illustrated articles described the localities in Australia where opals are found and also the methods used to mine them.[7] At Coober Pedy, the largest field in South Australia, heavy equipment such as bulldozers, is used to supplement the pick and shovel common to other areas. Two other major areas are Ankamooka, also in South Australia, and Lightning Ridge in New South Wales. Opal prices varied, depending on quality, from about $1 per ounce for the lowest grade of crude to $1,200 per ounce for excellent quality. Top grade opal in larger pieces up to 1 ounce in size sold for nearly $3,000 per ounce.

Botswana.—The Orapa mine of the De Beers Botswana Mining Co., (Pty.) Ltd., produced an estimated 2,718,000 carats of diamond from 2,954,000 tons of ore treated or 92 carats per ton treated.[8] Gem stones were about 15% of the yield. Sampling of kimberlite pipes, DK 1 and DK 2, by De Beers was completed but negotiations on further development were still in progress. The Government of Botswana has requested a review of terms for the Orapa mine.[9] Drilling was continued in several kimberlite pipes in southern Botswana.

Brazil.—The only large mechanical operation, Mineração Tejucana, S. A., reported production of 65,861 carats of diamond from 8.6 million cubic yards of gravel dredged and treated during 1973. Average sales price was $33.81 per carat. Production was about equally divided between gem and industrial stones.

The Brazil National Department of Mineral Production published its first bulletin on prices of minerals and metallurgical products for the period of January to March 1974. For precious and semiprecious stones the price list gave a range for the various qualities and median price f.o.b. Rio de Janeiro for diamond, aquamarine, emerald, chrysoberyl, citrine, amethyst, topaz, morganite, kunzite, garnet, opal, alexandrite, and tourmaline.

Central African Republic.—The 1974 diamond production attained a level about one-fifth higher than that of 1973. About two-thirds of the output was gem stone diamond by weight; and by value, gem stone diamond was more than 90%. Diamond exports accounted for about 35% of the foreign exchange receipts. Société Centrafricaine d'Exploitation Diamantifére was formed as a joint enterprise in 1973 by Diamond Distributors International, Inc., of New York, Cominco, Ltd., of Canada, and the Government to mechanize mining operations as well as to aid diggers. The joint enterprise was credited with the gains for 1974.

Ghana.—The Ghana Department of Mines reported diamond production of 2.3 million carats in 1973, a decline from

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Total (gem plus industrial) diamond output for each country is actually reported except where indicated by footnote to be an estimate. In contrast, the detailed separate reporting of gem diamond and industrial diamond represents Bureau of Mines estimates in the case of every country except Central African Republic (1972 and 1973), Lesotho (1972 and 1973), Liberia (all years), Guyana (1972 and 1973), and Venezuela (1972 and 1973), where sources give both total output and detail. The estimated distribution of total output between gem and industrial diamond is conjectural in the case of a number of countries, based on unofficial information of varying reliability.

[2] Exports of diamond originating in Lesotho; excludes stones imported for cutting and subsequently reexported.

[3] Exports.

[4] Revised from data in previous edition, which were for years ending August 31 of year stated, to normal calendar year basis.

[5] All company output from the Republic of South Africa except for that from the Premier mine; also excludes company output from the Territory of South West Africa and Botswana.

the 2.7 carats produced in 1972.[10] Since 1968, the average annual production from Ghana's two diamondiferous areas, the Birim River Basin (Eastern Region) and the Bonsa Region (Western), has averaged 2.47 million carats. Three companies, Ghana Consolidated Diamonds, Ltd., Cayco (Ghana) Ltd., and the Amalgamated Diamond Corp., are actively engaged in mining diamonds in the Birim River Basin. First International Natura Corp. of the United States completed exploration in the Birim and Pra River areas, and it was reported the firm would be issued a license for a project in which the Government will own a 55% share. Since the liquidation in 1969 of Takrowase Diamond Field, the Government has preferred participation rather than outright ownership in diamond mining operations. Effective from October 1, 1972, the Government acquired by decree a 55% interest in Consolidated African Trust's Ghana diamond operations by forming Ghana Consolidated Diamonds Ltd., in which Consolidated African Selection Trust Ltd. has a 45% share. Ghana Consolidated Diamonds Ltd. production in the 5-year period, 1968–73, was 2.39 million carats, or about 96% of the country's production, according to Ghana's Mines Department. The output averages about 10% gem stones of high quality.

Kenya.—A pink corundum deposit was claimed to be possibly the largest ruby mine in the world and was also the subject of dispute between Government administrators and geologists from the United States who made the original discovery.[11] According to the reports, about 300 kilograms of corundum were exported in the first 9 months of 1974 and were worth between $30,000 and $40,000 or over $100 per kilogram. The mine is located in the Tsavo National Game Park in southeastern Kenya.

Lesotho.—On March 1, 1974, an announcement was made that De Beers Diamond Corp. and the Government of Lesotho (GOL) reached an agreement in principle on opening the Letseng-la-terai diamond mine in the Maluti mountains at an estimated cost of over $30 million.[12] The agreement was to be signed early in 1975.[13] GOL will have a 25% equity in the corporation and will receive 62.5% of profits after recovery of invested capital. If the mine were to prove substantially more profitable than anticipated, the GOL percentage of profits could rise on a sliding scale to a maximum of 72%. Production is expected to start in 1977 at a rate of 4,000 tons of ore per day. A diamond sales company registered in Lesotho will be established and, throughout the life of the mine, the production will be marketed through the Central Selling Organization.

South Africa, Republic of.—In April 1974 a miner found a 616-carat gem diamond in the crusher at the Dutoitspan mine in the Kimberley area.[14] The diamond is the ninth largest gem diamond ever found and is the largest found in the Kimberley area. The announcement by De Beers said that the diamond was a yellow octahedron of good shape but not of the best quality.

Diamond sales by the Central Selling Organization decreased from R921 million ($1,289.4 million) in 1973 to R849 million ($1,288.6 million) in 1974, or 7.8%. Production of the larger and more valuable stones from all mines, old and new, declined. Generally, the increased demand for small diamonds was insufficient to offset the drop in value due to lower sales of large diamonds.

Sri Lanka.—The State Gem Corporation established a gem export incentive program under which exporters could reserve 25% of their gem value in unrestricted external accounts. The program created a boom in gem stone mining because all other segments of the business population, in addition to those already in the gem stone industry, joined in the export market to have access to the trade privileges. Gem stones in 1973 ranked fourth after tea, rubber, and coconut products in value of exports and were expected to rank second in 1974, exceeded only by the value of tea. Prior to 1973, gem stones contributed little to the total export value of Sri Lanka, but the 20-fold increase of the value in 1973 compared with that of 1972 raised the value of gem stones into the top rankings. Gem stones of interest to collectors include sapphire, ruby, garnet, catseye, spinel, moonstone, alexandrite, tourmaline, and varieties of quartz.

Thailand.—Major gem stones mines in Thailand are located in the provinces of Chantaburi, Kanchanburi, Phrae, Si Saket, and Trat.[15] The following types of gem stones are found: Ruby, sapphire, spinel, peridot, garnet, zircon, beryl, tourmaline, jadeite, quartz, and occasionally diamond. A high-volume of jade and rough sapphire stones are imported and reexported as cut stones because of the lower labor costs in Thailand. The majority, about 85%, of Thai gems are sold as cut stones. In Bangkok, the average prices for cut stones late in 1973 were $500 per carat for ruby, $380 per carat for blue sapphire, and $70 per carat for yellow sapphire. In 1957 gem stone exports amounted to about $380,000 but in 1973 the total value was about $31.0 million.

TECHNOLOGY

The world's third largest rough diamond—the 968.9-carat Star of Sierra Leone—was cut into 11 fine white gem stones ranging from 143.2 carats to 1.85 carats.[16] The total weight of the cut stones was 328.14 carats, a recovery of 33.9% comparing favorably with previously cut large stones.

Two color-illustrated articles described in detail the effects of either gamma radiation or heat treatment on the resulting gem stone colors.[17]

Colorless to pale-yellow topaz turned to a sherry color (imperial topaz) or to brown; however, an occasional topaz turned blue when irradiation was followed by heating. When colorless quartz was gamma-irradiated, it had a smoky or amethyst color, depending on the iron and aluminum content as well as the growth direction. Some natural colorless or pale-color beryl turned a deep-blue color after radiation, but the color was unstable on exposure to light. Similar dosages of gamma irradiation induced major color changes in tourmaline, but the stability of these colors was unpredictable on exposure to light or heat. An unstable new color in some Brazilian crystalline quartz was produced by gamma irradiation followed by gentle heating techniques. Pearls, a gem stone material, turned gray, bluish-gray, or blue by gamma irradiation and were stable. Kunzite turned a deep green after gamma irradiation but bleached on exposure to light or after heating. Minor color changes apparently were produced in jade and no changes appeared in opal after irradiation.

Technological progress in the use and application of lasers and grasers (X-ray laser) in gem stone analyses was reported.[18] Items of significant progress were as follows:

1. High-output laser systems have processed a variety of materials including plastic, metal, stone, and minerals.
2. Laser interferometry, holography, and acoustical holography have been used for the nondestructive testing of materials.
3. The X-ray laser or graser has been used in research and may lead to knowledge of the molecular structure of matter but it is extremely dangerous to use.

The first International Kimberlite Conference was held in the Republic of South Africa and Lesotho September 17 through October 8, 1973.[19] The conference of about 200 delegates from 20 countries brought together geologists who have an interest in the discovery of kimberlites, which can be the source rock for diamond.

[19] Boyd, F. R. Kimberlite Conference in Africa. Geotimes, v. 19, No. 5, May 1974, pp. 24–25.

The eruption of kimberlites in various parts of the world has brought an unusual variety of rock to the surface from the upper mantle and crustal basement. Southern Africa is rich in kimberlites, and the kimberlite occurrences in the small country of Lesotho alone amount to 17 pipes, 21 dike enlargements, and more than 200 dikes.[20]

A guide to collecting in working and abandoned mines was published and strongly emphasized attention to safety.[21] The publication was directed towards the experienced mineral collector who occasionally has the opportunity to go underground.

Gold

By J. M. West [1]

The price of gold on the open market reached an alltime high, approaching $200 per troy ounce for a brief interval at the end of 1974. Selling prices in New York averaged $159.74 per ounce, 63% higher than the 1973 average. The official gold price, at which Government gold was valued, remained at $42.22 per ounce. Prices were influenced by the expectation that the U.S. Government would remove restrictions on gold ownership by its citizens. A law permitting private ownership was passed in August 1974 and this provision of the law became effective on December 31, 1974. The upswing in prices was limited by several factors: Uncertainties about the levels of demand of the newly created private sector at yearend; declining commercial demand owing to recession; the announcement in December that 2 million ounces of Treasury gold would be offered for public sale on January 6, 1975; sharply increasing imports of gold coins (important restrictions were removed in December 1973); and the introduction of gold futures trading at yearend, which tended to substitute for direct purchase and physical acquisition of the metal.

Supplies of gold to U.S. markets were supplemented by sales of foreign Government-owned gold from stocks on deposit at the Federal Reserve Bank in New York. Sales amounted to 2.14 million ounces in 1974, up 0.45 million over those in 1973. Gold coin imports were estimated to have totaled 3.09 million ounces valued at $552 million. Total gold imports were down 31% in 1974, to 2.65 million ounces, but imports in unrefined form were up 40% to 0.33 million ounces. Domestic mine production declined for the fourth straight year to 1.13 million ounces, a 4% drop. The leading producer was once again the Homestake mine, a deep underground operation of the Homestake Mining Co. in Lead, S. Dak. This also made South Dakota the leading State in gold output. Nevada, with the Carlin and Cortez mines supplying most of the State total, was second and Utah, third. The three States accounted for 80% of total mine production.

Domestic demand for gold dropped 31% in 1974, with jewelry and arts accounting for 52%; dental, 11%; and other uses (mainly electronic), 37% of the total consumed. Inventories of gold in refiners', dealers', and manufacturers' hands declined 178,000 ounces (4%) during the year until December when an estimated 1.35 million ounces was acquired by dealers to meet anticipated new demands after ownership restrictions were rescinded.

Elaborate plans were made by fabricators and dealers to market new gold products in many forms, weights, and varieties of packaging directed toward investment purchases. New sales arrangements were made between traditional suppliers and dealers, some of whom had little previous experience in selling gold. "Certificate plans" were introduced for installment purchases, and estimates of 1975 gold demand for private holding were reported variously but generally between 5 and 15 million ounces. At yearend, five new futures exchanges for gold opened, two in New York and the others in Chicago.

World gold supplies declined, with production down 7.5% to 39.8 million ounces. The Republic of South Africa produced 61% of the world total in 1974, its production dropping 11% compared with 1973 output. U.S.S.R. production was significantly higher in 1974 and accounted for 18% of world output. Canada ranked third and the United States, fourth.

[1] Physical scientist, Division of Nonferrous Metals.

Samuel Montagu & Co. Ltd., in its Annual Bullion Review 1974, estimated new gold supplies for the year, in million ounces, as follows: From new production (excluding U.S.S.R.), 32; U.S.S.R. sales, 7.4; and other sources, 5.6. Distribution of the "offtake" was reported, as follows, in million ounces: Europe, 15.1; United States, 7.7; Far East, 3.7; Middle East, 1.1; Latin America, 1.3; rest of world, 1.1; and additional amounts to investors, 15.0. Total supply and demand was estimated at 45 million ounces, 55% from the Republic of South Africa and 16% from the U.S.S.R. World consumption of gold in jewelry was estimated to have declined 40% in 1974 but this was offset by a five-fold increase in sales of gold coin, particularly in Europe and the United States. European industrial consumption was down 42%, to 8 million ounces. Demand for private holding and investment was estimated to have increased sharply to 27.3 million ounces; 8.3 million ounces of this was estimated to have gone into the manufacture of gold coins (Republic of South Africa, 35%; Austria, 26%; Mexico, 23%; Hungary, 6%; United Kingdom, 5%). Because of booming coin markets, the Republic of South Africa announced its coinage of the Krugerrand, containing 1 troy ounce of gold, would be expanded to a rate of 150,000 per week early in 1975, which would consume nearly 30% of the country's mine production of gold. Krugerrand sales in 1974 were 3.2 million, including 1.1 million to West Germany, 0.9 million to the United Kingdom, and 0.7 to Switzerland.

Table 1.—Salient gold statistics

	1970	1971	1972	1973	1974
United States:					
Mine production thousand troy ounces	1,743	1,495	1,450	1,176	1,127
Value thousands	$63,439	$61,673	$84,967	$115,000	$180,009

r Revised.

[1] From domestic ores—U.S. Department of the Treasury.

[2] Excludes coinage.

[3] Includes gold in Exchange Stabilization Fund.

[4] Engelhard selling quotations.

[5] Held by central banks and governments in market economies; gold valued at $35 per troy ounce in 1970, $38 per ounce in 1971–72, and $42.22 per ounce in 1973–74.

Energy consumed in producing gold.—Results of a Bureau of Mines survey of energy requirements in gold mining (1973) completed in 1974 showed that on a per ounce of gold basis placer mining consumed nearly 4 times the energy consumed in lode gold mining. The relatively high consumption in placer operations was generally attributed to the necessity to move large quantities of materials by mechanical means at existing mining localities. A total of 218 reporting gold mine operators consumed 154.2 million kilowatt-hours of electricity (purchased), 2.3 million cubic feet of natural gas, and petroleum products, as follows, in thousand gallons: Heavy fuel, 17; diesel and light fuels, 2,168; gasoline, 514; and other, 26. Generally, about two-thirds of the energy was consumed in mining; one-third went to related smelting, beneficiation, and other purposes. Explosives for mining and energy needed for refining were not considered in the survey.

Legislation and Government Programs.—Public Law 93-373, enacted August 14, 1974, provided for removal of restrictions on U.S. citizens buying, holding, and selling gold. The pertinent section of the Act read as follows:

> Sec. 2. Subsections 3 (b) and (c) of Public Law 93-110 (87 Stat. 352) are repealed and in lieu thereof add the following:
>
> "(b) No provision of any law in effect on the date of enactment of this Act, and no rule, regulation, or order in effect on the date subsections (a) and (b) become effective may be construed to prohibit any person from purchasing, holding, selling, or otherwise dealing with gold in the United States or abroad.
>
> "(c) The provisions of subsections (a) and (b) of this section shall take effect either on December 31, 1974, or at any time prior to such date that the President finds and reports to Congress that international monetary reform shall have proceeded to the point where elimination of regulations on private ownership of gold will not adversely affect the United States' international monetary position."

Restrictions were removed accordingly on December 31, 1974.

In anticipation of the public interest in purchasing gold, the Securities Exchange Commission (SEC) issued release No. 11125 on December 9, entitled "SEC Statement On Gold Ownership," which provided advice on purchasing gold and to whom complaints of deceptive practices should be directed. Copies were available from the SEC, Publications Section, 500 North Capitol Street, N.W., Washington, D.C. 20549.

Section 217 of Public Law 93-463, enacted October 23, 1974, provided for regulation by the newly established Commodity Futures Trading Commission of transactions for the delivery of silver bullion, gold bullion, or bulk silver and gold coins pursuant to a standardized contract. Under the section, effective April 21, 1975, all persons would be forbidden to offer to enter into or confirm the execution of any contract contrary to any rule, regulation, or order of the Commodity Futures Trading Commission.

The Secretary of the Treasury, by Treasury Department Order No. 234, dated December 18, 1974, authorized the public sale of 2 million fine troy ounces of gold on January 6, 1975. The sale was conducted by the General Services Administration's Office of Stockpile Disposal and carried out by sealed bids accompanied by a 5% deposit. The minimum bid was placed at 400 fine troy ounces, and the Government reserved the right to reject any and all bids.

As in previous years, the Office of Minerals Exploration, U.S. Geological Survey, conducted its program of participatory loans for domestic gold exploration projects, providing up to 75% of approved costs for a few qualifying operators.

DOMESTIC PRODUCTION

Reduced domestic gold production during the year resulted partly from declining byproduct gold output at copper mines and from lower output at the Homestake mine in South Dakota. Nevada output, however, was 15% higher than in 1973 owing to increased recoveries from leaching and milling operations of Cortez Gold Mines in Lander County and from expanded activities of Carlin Gold Mining Co. in Eureka County. Production declined at the Knob Hill mine in Washington owing to nearly depleted ore reserves. In Alaska, an increasing number of placer operations contributed to production.

In many gold mining areas of the country, there were reports of renewed gold prospecting and development activities, with plans revealed for significant investments in new production facilities. States with the greatest activity were Nevada, Colorado, California, Alaska, New Mexico, Idaho, and Montana, about in that order. Others included Utah, South Dakota, Oregon, Washington, Arizona, Georgia, and North Carolina. Projects with potential for producing 580,000 ounces of gold per year were expected to come into production in the 1975–77 period.[8]

The four leading U.S. gold producers provided 75% of total production in 1974; 97% of all production came from 25 mines, only 6 of which were operated primarily for gold. Placers contributed only about 1% of production, as in 1973, but the number of placer mines reported decreased to 43 compared with 71 in 1973. The largest placer producer was UV Industries, Inc., operating a bucketline dredge at Hogatza, Alaska. Part of the placer output continued to come from sand and gravel operators in California and Colorado. About 41% of total gold production was a byproduct of other mining.

An estimated 1.9 million ounces of secondary gold was produced by refiners, compared with 1.8 million ounces in 1973. Amax, Inc., with refining facilities at Carteret, N.J., continued as the largest U.S. refiner of gold, reporting output of 973,300 ounces in 1974, mostly produced under toll agreements. Production was 19% higher than in 1973. Kennecott Copper Corp. reported refinery production of 280,561 ounces in 1974 versus 342,284 ounces in 1973.

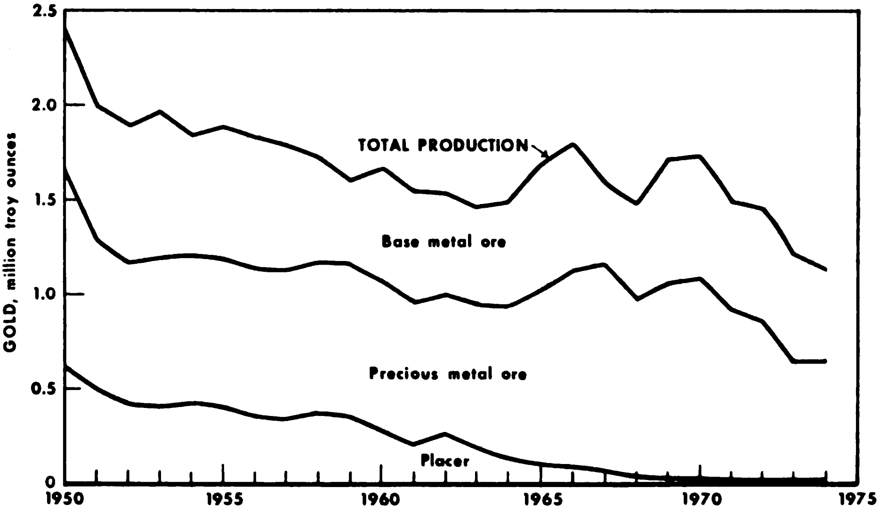

Figure 1.—Sources of U.S. gold production.

Homestake Mining Co. reported a 4% drop in production to 343,650 ounces. The average price received on sales was $157.96 per ounce compared with $93.36 in 1973. Revenues from sales from the Homestake mine were $47.9 million versus $32.9 million in 1973. The average recovered grade of ore was 0.220 ounce per ton compared with 0.227 ounce per ton in 1973, a 3% drop. A total of 1.56 million tons of ore was milled, slightly less than in 1973 but metallurgical recovery was improved to an average 95.12% compared with 93.63% in 1973. A reduced supply of miners continued to limit tonnages mined. Work began on deepening the No. 6 winze and advanced 517 feet to a depth of 7,729 feet below surface by yearend. Sinking of the No. 7 winze from the 6,800-foot level was expected to start by mid-1975. The winzes will provide access to the 8,000-foot level. Exploration crosscuts were driven toward the western parts of the mine. Ore reserves at yearend were estimated at 15.45 million tons averaging 0.262 ounce per ton compared with 15.87 million tons averaging 0.280 ounce per ton a year earlier; 57% was classified as proven ore. Company employment was 1,600 in total, of which 1,067 employees were in the mining department.

---

[8] Melbye, C. E. New U.S. Discoveries and Expected Mine Production. Paper pres. at 1975 Internat. Monetary Symp., Miami Beach, Fla. Jan. 7, 1975. (Copies available from Minerals Engineering Co., Denver, Colo.).

At the Carlin mine in Nevada, 160,500 ounces of gold was produced, 7% more than in 1973. Sales were valued at $26.5 million compared with $15.0 million in 1973; net income from the Carlin operations rose 93%, to $10.9 million. The grade of ore averaged 7% higher in 1974 than in 1973, at 0.223 ounce per ton and slightly less ore, 824,000 tons, was milled. The total tonnage of material mined was 6.27 million tons including waste from stripping. Minable ore reserves at yearend were 4.18 million tons, averaging 0.233 ounce per ton (including Bootstrap and Blue Star mines), and an additional 0.99 million tons of somewhat higher grade ore was revealed by drilling the flanks of the existing Carlin pit area. Exploration continued on deeper portions of the Carlin deposit in ores with a relatively high-carbon content, generally more costly to mill. Mining began at the Bootstrap and Blue Star properties, where reserves totaled 2.1 million tons averaging 0.15 ounce per ton, which were destined for the Carlin mill. Also, the properties contained 0.5 million tons of 0.02 to 0.04 ounce grade to be subjected to heap-leach extraction.

Mining continued at Cortez Gold Mines Gold Acres property and, with higher prices, was resumed at the Cortez open pit mine in Nevada, but reserves were estimated only sufficient to sustain milling until mid-1975. During 1974, 853,500 tons of ore was milled averaging 0.116 ounce per ton, with recovery of 81.8%. Milling provided 81,200 ounces of gold versus 65,400 ounces in 1973, and heap-leaching provided 23,100 ounces versus 10,300 ounces in 1973. About 4 million tons of heap-leachable material was under treatment, with recoveries estimated to date of 64% at Cortez and 50% at Gold Acres. Further exploration was in progress at Gold Acres.

All assets in Alaskan gold operations of UV Industries, Inc. were exchanged for stock in a wholly owned subsidiary, Alaska Gold Co., as of January 1, 1975. The firm continued to operate a gold dredge at Hogatza and prepared to renew dredge operations in the Nome area of Alaska in 1975. Gold reserves in the Nome area were estimated at 1.19 million ounces, including 66,400 ounces added in recent drilling. An additional 78,800-ounce reserve was estimated from recent exploration 5 miles west of Nome. Thawing of frozen ground continued in advance of dredging.

Among developments in 1974, the Ajax shaft of the Golden Cycle Gold Corp. near Cripple Creek, Colo., was sunk to the 3,350-foot level and mill reconstruction was in progress. Test work was completed by other companies on heap-leaching projects at Round Mountain and Manhattan, Nev., and production scale operations were scheduled. A bucket-line dredge was scheduled to renew operations early in 1975 at Hammonton, Calif. Studies were progressing on significant new cyanidation projects at the Getchell mine, Humboldt County, Nev.; the Pinson-Prebel mine, also in Humboldt County; portions of the Comstock Lode, Storey County, Nev.; the Delamar mine, Owyhee County, Idaho; and the Golden Sunlight mine, Jefferson County, Mont. The Atlanta gold-silver mine, in Lincoln County, Nev., was scheduled to return to production in April 1975 at an annual rate of 13,500 ounces of gold and 65,000 ounces of silver. The mine will be operated by Standard Slag Corp. and will be worked by open pit methods.

CONSUMPTION AND USES

U.S. gold consumption, based on estimated net purchases of gold by U.S. industry, reported by the Office of Domestic Gold and Silver Operations, U.S. Department of the Treasury, was 4.65 million ounces, 31% lower than in 1973. Purchases were divided by industrial groups, as follows, in thousand ounces (with 1973 figures for comparison): Jewelry and arts, 2,402 (3,473); dental, 509 (679); and industrial, including space and defense, 1,740 (2,577). All categories were lower owing to the recession. About 48% of total purchases were made in the first half of the year and 52% in the last half. Excluded from the statistics was an estimated 1.35 million ounces required by refiners and dealers in December 1974 to meet expected demand by individuals following the end of ownership restrictions.

In addition to bullion consumption, U.S. buyers purchased an estimated 3.09 million ounces of imported gold coins in 1974, much higher than in 1973. The value of these coins was reported at $552 million during 1974, 39% marketed in the first half and 61% in the second half of the year.

Owing to higher prices for gold, there were increased efforts to substitute less expensive metals and to apply gold to products only where specifically necessary. In jewelry, more sales of heavy plated gold were reported and less of karat gold, which is more expensive and contains much more gold. Silver jewelry sales were reportedly making inroads on gold jewelry sales because of changes in buyers attitudes and the introduction of new silver jewelry items. Use of clad metal inlays for electronic connections was expanding, with increased knowledge of physical and electrical properties of various alloys.[3] Potential for a sharp drop in contact consumption of gold was foreseen. Substitution of low-gold and nickel-based alloys for 82% gold-18% nickel alloys commonly used in high-temperature brazing was under study.[4]

Use of thin gold films on window panes as protection from solar radiation and to reduce fuel costs was described.[5] The gold was applied by vacuum-film methods; sheets up to 100 square feet in area were treated, with glass available in various shades of blue, gold, and bronze. Gold films were also considered useful in devices converting solar energy, and a significant role for gold was seen in this application.[6]

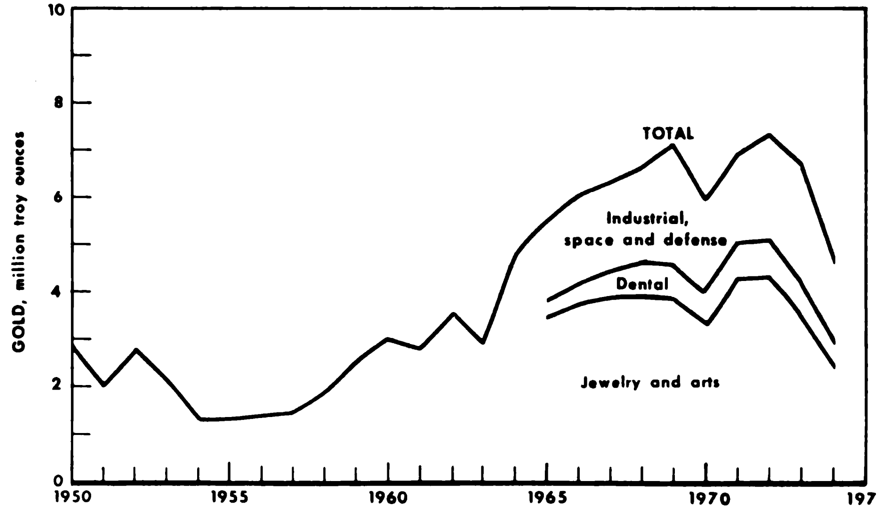

Figure 2.—Gold consumption in the United States.

STOCKS

Monetary.—U.S. official gold stocks (including stocks in the Exchange Stabilization Fund) remained the same all year at 276.0 million ounces valued at $11,652 million ($42.22 per ounce). Inconvertability of dollars to gold remained in effect.

Earmarked gold held in Federal Reserve banks for foreign official accounts was valued at $16,838 million at the end of December, equivalent to 398.8 million ounces, 5.5 million ounces less than at the end of December 1973.

Total gold reserves of all central banks and governments (excluding those of centrally planned economies) were estimated by the Federal Reserve Bank at $49,795 million in value at yearend 1974 compared with $49,850 million a year earlier. The major countries or institutions holding stocks, with equivalent million ounces at the end of 1974, were, as follows: The United States, 276.0; International Monetary Fund (IMF), 153.4; Federal Republic of Germany, 117.6; France, 100.9; Switzerland, 83.2; Italy, 82.5; the Netherlands, 54.3; Belgium, 42.2; Portugal, 27.9; Canada, 22.0; Japan, 21.1; the United Kingdom, 21.0; Austria, 20.9; the Republic of South Africa, 18.3; and Spain, 14.3. Stocks totaled 1,179.4 million ounces. South African stocks declined 0.78 million ounces during 1974, partly owing to increased coinage. Mexican stocks declined about 1 million ounces for the same reason. Kuwait and Portugese stocks rose 0.7 and 0.4 million ounces, respectively, during the year. The U.S.S.R. stocks were believed to have remained about the same in 1974 at between 60 and 65 million ounces, with production approximately equaling the sum of consumption and sales.

[5] Groth, R., and W. Reichelt. Gold Coated Glass in the Building Industry. Gold Bull., Chamber of Mines of South Africa, v. 7., No. 3, July 1974, pp. 62-68.

[6] Brinkworth, B. J. Gold Films in Solar Energy Utilisation. Gold Bull. v. 7, No. 2, April 1974, pp. 35-38.

Special Drawing Rights (SDR's) holdings for all countries in the IMF were valued at $10,845 million at the end of 1974 compared with $10,625 million a year earlier. The U.S. reserve position in the Fund was $1,852 million at the end of 1974 compared with $552 million a year earlier. The dollar value of an SDR was $1.2243 at the end of 1974 compared with $1.2064 a year earlier. Changes in the value of the SDR after July 1, 1974, were determined from changes in the value of a "basket" of the currencies of 16 countries whose exports in 1968–72 constituted 1% or more of world exports. The new values were determined daily by valuing the currencies in the basket on the basis of their exchange rates on the London Market. Prior to July 1974 the SDR was valued according to the official price of gold and was equivalent to 0.888671 gram of fine gold by definition.

Industrial.—Domestic gold inventories as reported by the Office of Domestic Gold and Silver Operations, U.S. Department of the Treasury, were as follows, in thousand troy ounces at yearend 1974 (with changes from yearend 1973): Refiners, 3,761 (up 28%); dealers, 1,004 (up 113%); and manufacturers, 905 (down 17%). Stocks included an estimated 1.35 million ounces acquired by refiners and dealers in December 1974 to meet expected demand by individuals following the yearend removal of restrictions on private ownership. Total stocks of 5.67 million ounces were 26% higher than at the end of 1973.

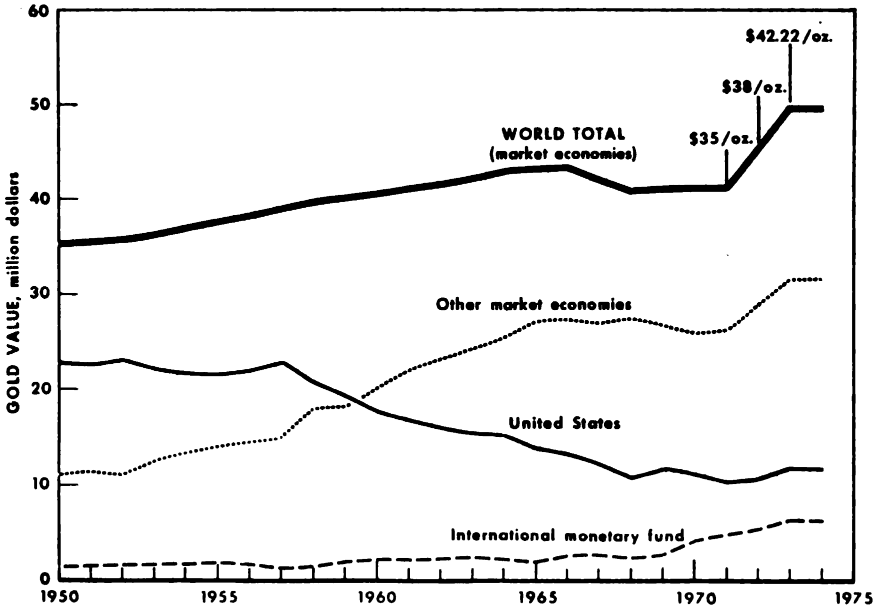

Figure 3.—World monetary gold stocks.

PRICES

Free market gold prices, as quoted daily by Engelhard Industries, rose from a low of $117.00 per troy ounce on January 2 to a high of $194.75 per ounce on December 27 and averaged $159.74 for the year. From December 27 to the end of the year, Engelhard suspended price quotations owing to impending changes in marketing methods planned as a result of removal of restrictions on gold sales. London prices during most of the year were about 50 cents lower than New York prices and the average London final price for the year was $159.259 per ounce. The highest London price was $197.50 at the initial fixing on December 30; the final price that day was $195.25 per ounce. On December 31, the London final price declined to $186.50.

Table 2 shows ranges and average prices for gold by month during 1974. Prices were influenced by a variety of events related to world monetary and economic uncertainties. Towards the end of the year, prices were influenced mainly by speculation that demand for gold would rise sharply as a result of the removal at year-end of restrictions on the holding of gold by U.S. citizens. However, the price rise was limited by the announcement that the U.S. Treasury would offer on an auction basis up to 2 million ounces of gold bullion in early January 1975. Subsequently, only 754,000 ounces of that offered was sold at an average price of $165.67 per ounce. The official gold price in the United States and most other countries remained at $42.22 per troy ounce, the price at which Treasury gold stocks were valued. No gold was bought or sold at this price, however.

Table 2.—U.S. monthly gold selling prices, per ounce

Month	1974		
	Average	Low	High
January	$129.69	$117.00	$141.50
February	150.75	131.00	175.50
March	168.92	159.50	178.00
April	172.81	167.50	180.00
May	163.77	154.50	170.15
June	154.60	144.75	162.25
July	144.11	137.00	158.00
August	155.12	152.00	159.90
September	151.93	145.90	158.25
October	159.29	154.50	168.75
November	182.47	168.20	191.00
December	183.48	174.75	[1] 194.75
Year	159.74	117.00	194.75

[1] No quotations were issued from December 27 to December 31.

FOREIGN TRADE

U.S. exports of gold in 1974 amounted to 3.86 million ounces valued at $228.5 million. Of the quantity exported, 3.30 million ounces was designated as monetary gold valued at the official rather than market price. Exports of monetary gold included 2.58 million ounces going to Saudi Arabia, 0.35 million ounces to Switzerland, 0.20 million ounces to Mexico, and 0.16 million ounces to Canada. The balance of the gold exported consisted of 0.31 million ounces of scrap and 0.26 million ounces of bullion. Most of the scrap went to Belgium (46%) and the United Kingdom (32%).

Gold imports totaled 2.65 million ounces valued at $396.7 million. Imports consisted of 0.33 million ounces of ore, base bullion, and scrap valued at $46 million and 2.32 million ounces of bullion valued at $350.7 million. Imports were 36% from Canada, 22% from the U.S.S.R., 17% from Switzerland, 6% from France, and 19% from 31 other countries. Average import values for bullion from the leading sources were as follows, per troy ounce: Canada, $150.38; the U.S.S.R., $144.10; Switzerland, $154.25; France, $162.66; the United Kingdom, $158.45; and Yugoslavia, $152.76. In addition to imports, gold markets were supplied with 2.14 million ounces from foreign government stocks stored at the Federal Reserve Bank in New York.

The net inflow of gold to U.S. markets (excluding monetary movements but including supplies from foreign stocks in New York) amounted to 4.23 million ounces in 1974 compared with 4.76 million ounces in 1973. In addition, an estimated 3.09 million ounces of gold was imported into the country in the form of gold coins during 1974. The inflow of unrefined gold was 7% more than the outflow in scrap in 1974.

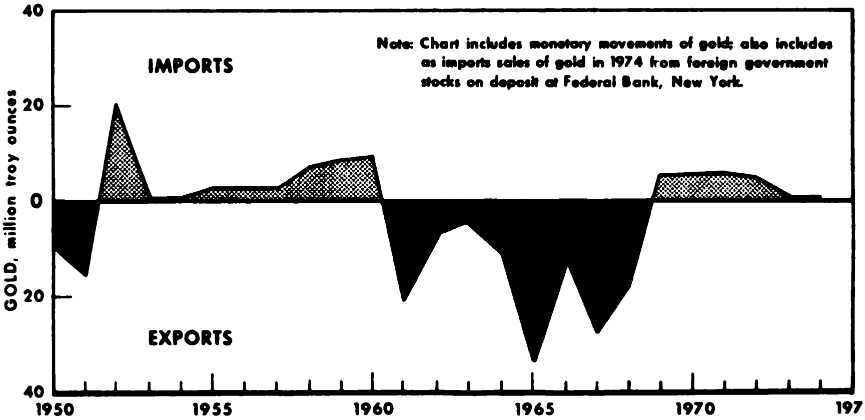

Figure 4.—Net exports or imports of gold.

WORLD REVIEW

Despite higher gold prices, world gold production declined for the fourth year to 39.8 million ounces, a 7.5% drop. The U.S.S.R. showed the only significant increase, with output rising 3%, to 7.3 million ounces, owing mainly to expanded open pit and lode gold mining operations at several large facilities. The Republic of South Africa produced about the same tonnage of ore as in 1973 but 11% lower in grade, hence, that much less gold production. Byproduct gold production was probably slightly higher than in 1973, but copper, the main byproduct source, was in less demand toward yearend 1974, and production cuts were expected to reduce this source of gold in 1975. A significant new producer was expected to come into production in the Dominican Republic early in 1975. Many past producing gold properties throughout the world were being reexamined in view of higher prices and possible utilization of new technology to reduce extraction costs.

World net gold consumption in fabricated products was estimated by Consolidated Gold Fields Ltd. at about 23 million ounces in 1974 compared with 27 million ounces in 1973, down 15%. Although jewelry uses dropped sharply, part of this drop was offset by a large increase in official gold coinage, which rose from 1.7 million ounces in 1973 to an estimated 9.2 million ounces in 1974. Significant increases in coinage took place in the Republic of South Africa, Austria, Mexico, Hungary, and the United Kingdom. Total net private purchases of gold were estimated at 40 million ounces, including 7 million ounces in net trade with the U.S.S.R. Samuel Montagu & Co. Ltd. estimated the world offtake of gold in 1974 at 45 million ounces, including 15 million ounces to investors. Private hoarding probably accounted for 10 to 11 million ounces of the offtake. European industrial consumption was estimated to have fallen 42%, to 8 million ounces, compared with that of 1973, with the sharpest decline in Italy. Gold in the form of scrap jewelry and bars was dishoarded in the Middle East and Far East in amounts estimated to total 4 million ounces in 1974, nearly twice that in 1973. The U.S.S.R. gold sales were estimated at 7.4 million ounces. The total world supply of gold was estimated at 45 million ounces. Mocatta and Goldsmid Ltd. estimated world consumption at 20.3 million ounces (excluding coinage) in 1974, 5.5 million ounces less than in 1973. Investments in coins accounted for an estimated 7.4 million ounces, up from 1.6 million ounces in 1973.

A brief review by countries follows:

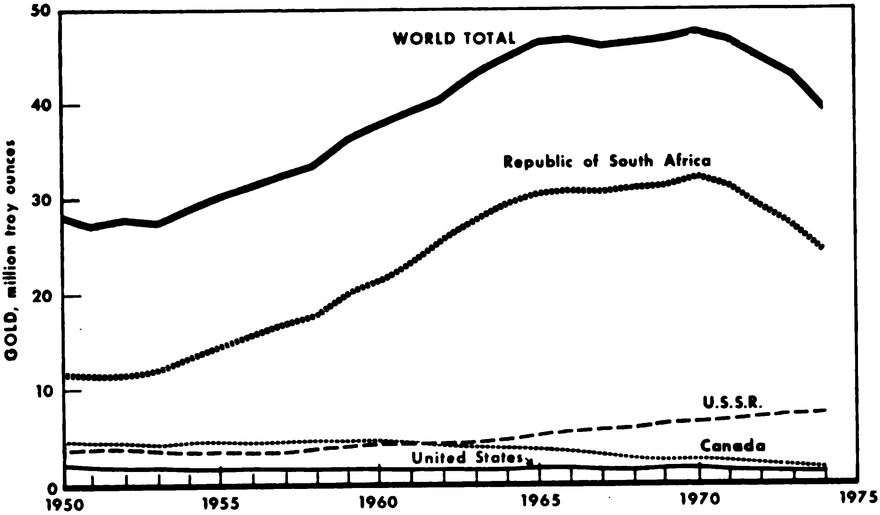

Figure 5.—World production of gold.

Angola.—Plans were announced by Chromalloy American Corp. to begin producing gold on a pilot scale about mid-1974 at its new Angolan property. High-assay values were reported on vein material, and production worth over $100,000 monthly was anticipated for at least 2 years and probably longer.

Argentina.—Yacimientos Mineros Aqua de Dionisio continued work on developing gold-silver-copper manganese deposits at Farallon Negro, Catamarca. Processing of 350 tons of ore per day was planned to produce annually an estimated 20,000 ounces of gold, 81,000 ounces of silver, and 25,000 tons of manganese concentrates.

Australia.—Australian gold production continued to come mainly from several gold lodes in Western Australia, the Kalgoorlie area providing about 432,000 ounces of output in the first 9 months of the year. Newmont Mining Corp. disclosed a feasibility study of its Telfer gold deposits in the Paterson Range of the Great Sandy Desert of Western Australia indicating ore reserves of 3.8 million tons averaging 0.31 ounce per ton which could be mined by an open pit. A tentative production schedule was set at about 200,000 ounces per year by yearend 1976. At Coolgardie, Western Australia, Roebourne Exploration and Mining Ltd. planned a gold mill after favorable feasibility studies. A 0.5-million-ton reserve averaging 0.38 ounce per ton was outlined in diamond drilling by Kia Oro Gold Corp. N.L. and Nickel Exploration Ltd. at the Marvel Loch gold mine near Southern Cross, Western Australia.

Bolivia.—South American Placers Inc. (SAPI) and the Tipuani Cooperatives operated placer mines at Teoponte and sold all production to the Central Bank as required by law. Sales were about the same as in 1973 when 14,187 fine troy ounces of gold was contained in 21,554 ounces of 95% pure placer product. As a result of a tax dispute, SAPI agreed to pay the Bolivian Government 751 troy ounces of gold and relinquished claims on alluvial areas that the firm had no existing plan to exploit. The settlement made possible negotiations to form a new company which will dredge placer deposits contiguous to SAPI's active properties at Teoponte. Camino Gold Mines Ltd. held options on 10,000 acres of placer property in the Tipuani River Valley and conducted sampling by a number of 3-foot-diameter test shafts. A pilot plant processed sample materials at the site.

Brazil.—The entire lode gold production came from operations of Mineracão Morro Velho S.A. in Minas Gerais. In addition there was unrecorded placer production estimated at about 13,000 ounces of gold per month, principally from the Amazon's Tapajos basin, where the Jamanxim River was the single richest area. The Madeira River in Rondônia was also reported promising enough to have attracted the interest of a mining company during the year. Another company was evaluating a mining venture at Guajará-Mirim, near the Bolivian border. Other active placer areas were on the Calcoene and Vila Nova Rivers in Amapá and on the Gurupi River between Pará and Maranhão States.

Canada.—Canadian gold production declined 12%, to 1.72 million ounces in 1974 and output was expected to be lower in 1975. The drop marked the fifteenth year in a row that gold production had declined. Output by Province, with change from 1973 (in parentheses) follows: Ontario, 46% (down 15%); Quebec, 26% (down 10%); Northwest Territories, 11% (down 30%); British Columbia, 11% (down 4%); Prairie Provinces, 4% (down 10%); Yukon, 1% (up 17%); and Atlantic Provinces, 1% (down 5%). Quartz lode and placer deposits provided 73% of total 1974 production; base metal mines supplied the balance. The average grade of ore at the end of 1974 for six gold mines in Quebec was 0.14 ounce per ton, with highest grade 0.18 ounce per ton. At the end of 1974, Canada had 22 mines classified as lode gold mines, the same number as a year earlier. Placer mining accounted for less than 0.5% of the 1974 production and was mostly in Yukon and British Columbia.

In Ontario, 11 lode mines accounted for 93% of Provincial production. Campbell Red Lake Mines Ltd. remained Canada's largest gold producer, yielding 197,369 ounces of gold from 289,833 tons of ore averaging 0.74 ounce of gold per ton in 1974. The main stoping areas were above the 2,200-foot level. During the year, about 21,000 feet of diamond drilling was done increasing ore reserves by 74,000 tons to 1.56 million tons.

Madsen Red Lake Gold Mines Ltd. sold its Red Lake, Ontario, mine and milling facilities to Bulora Corp. for $1.7 million and Bulora planned $0.5 million expenditures for development and exploration. Dickenson Mines Ltd. explored with favorable results at a depth of about 5,000 feet and at midyear had reserves of 346,600 tons averaging 0.46 ounce per ton in the Dickenson mine and 103,900 tons averaging 0.72 ounce per ton in its Robin Red Lake property. Wilmar Mines, Ltd., owned by Cochenour Willans Gold Mines Ltd. and Martin-McNeely Mines Ltd., found a new ore body at its Red Lake property with reserves estimated at 5 million tons averaging 0.15 ounce per ton in gold. A feasibility study was underway for reopening and expanding the Cochenour mill to a 2,000-ton-per-day capacity to handle production.

Nudulama Mines Ltd., controlled by Coniagas Mines Ltd., planned to reopen its mine, idle since 1952 in Lesueur Township, in the Missanaibi area of Ontario. Ore reserves were reported at 579,000 tons averaging 0.194 ounce per ton. Rengold Mines Ltd. leased the Renabie property of Willroy Mines Ltd. and planned extensive exploration. Consolidated Professor Mines Ltd. planned a $1.5 million development program at its Duport gold mine at Shoal Lake, in the Kenora area of northwestern Ontario. A 300-ton-per-day production rate was considered. Pursides Gold Mines Ltd., subsidiary of Ballinderry Explorations Ltd., dewatered its Wawa area gold mine and began exploration. Lakelyn Mines Ltd. planned a 100,000-ton-per-year operation at Lingman Lake based on reserves of about 0.8 million tons grading between 0.21 and 0.41 ounce per ton.

In Quebec, Agnico-Eagle Mines Ltd. produced at a rate of 800 tons per day of ore grading 0.27 ounce per ton from its Joutel gold mine and expected to reach 1,000 tons per day early in 1975 after solving a production problem with its high sulfide ore. Goldex Mines Ltd. completed installing equipment at its Dubuisson Township, Quebec, gold mine. The mine was developed by a 2,400-foot inclined shaft and lateral drifts; ores will be treated at the nearby Malartic Gold Fields Ltd. mill. Camflo Mines Ltd. increased mill capacity to 1,250 tons per day in Northwest Quebec and deepened its shaft to 3,350 feet, adding four production levels. Ore reserves at yearend were about 3 million tons grading 0.19 ounce per ton. Gold Hawk Mines Ltd. reported that its Dasserat, Quebec, property under lease to Somed Mines Ltd., contained reserves of 1.6 million tons grading 0.28 ounce per ton. Somed was reportedly planning to proceed with development and to ship

80,000 tons of ore to the nearby Kerr Addison Mines Ltd.'s mill. Gold Hawk also completed a diamond drill program at Cadillac, Quebec, and planned underground work. Chibex Ltd. began mill operations late in 1974 in the Chibougamau district at a rate of 500 tons per day. Sigma Mines Ltd. milled 498,410 tons of ore in 1974 and recovered 73,019 ounces of gold. Ore reserves were estimated at 1.25 million tons, and a shaft-deepening program was completed adding four new levels at 200-foot intervals from the bottom of the 5,962-foot main shaft.

The number of gold quartz and placer claims in the Yukon Territory rose sharply in 1974, indicating increased prospecting activities. Most placer claims were in the Dawson Mining Division. In the Northwest Territories, Giant Yellowknife Mines Ltd. produced 101,514 ounces of gold from 328,099 tons of ore milled in 1974 and reported yearend ore reserves in its Giant, Lolor, and Supercrest deposits at 2.4 million tons averaging 0.33 ounce per ton. About 10% of the Giant production in 1974 was from an open pit containing an estimated 480,000 tons of ore grading 0.3 ounce per ton. Cominco Ltd. continued sinking a 5,800-foot shaft at its Con property in the Campbell-Giant shear zone and planned additional exploration in the Yellowknife Bay area. Arcadia Explorations Ltd. explored a promising prospect, the Coronation Gulf, near the Western Arctic Ocean, 380 miles north of Yellowknife. In British Columbia, Northair Mines Ltd. planned a 300- to 400-ton-per-day mill at its Brandywine Falls property, 70 miles north of Vancouver, based on an estimated reserve of 400,000 tons averaging 1.05 ounce of gold per ton. The Unicorn gold-silver mine, north of Stewart, British Columbia, was reopened by Tournigan Mining Explorations Ltd. Other gold properties being explored included the Surf Inlet, northwest of Vancouver on Princess Royal Island; the Carolin Mines Ltd. property, northeast of Hope, where 1 million tons of 0.1-ounce-per-ton ore was outlined; the Carolin Mines Ltd. property near Lardner Creek, also northeast of Hope; and the Kalco Valley Mines Ltd. property on the Unuk River, 60 miles north of Stewart, B.C.

Colombia.—Mineros Colombianos S.A., a group of Colombian investors, purchased Cia. Minera Chocó Pacífico, S.A., a gold dredging firm, from International Mining Corp. about the end of May. Purchase of Pato Consolidated Gold Dredging Ltd. was also under consideration. International Mining retained a technical assistance contract with the new owners.

Costa Rica.—Reserves estimated at 70,000 tons averaging 0.44 ounce per ton were reported at the Bellevista-Montezuma gold property of New Taku Mines Ltd. (Canada). A change in the company name was planned to Gold Ventures Ltd., and a 150-ton-per-day mill was expected to be operational by yearend 1974. Bonnacord Explorations Ltd. (Canada) optioned a placer property covering nearly 4 square miles on the Peninsula de Osa and established a base camp for exploration to begin late in 1974.

Dominican Republic.—A large, new gold-silver mine, the Pueblo Viejo, of Rosario Dominicana, S.A. (parents, Rosario Resources Corp. and Simplot Industries, Inc.) was expected to begin production early in 1975 after delays in delivery of equipment. The cyanidation plant will treat 8,000 tons of ore daily producing 350,000 ounces of gold and 1.5 million ounces of silver annually. Reserves of oxide ore are established at 30 million tons averaging 0.128 ounce of gold and 0.82 ounce of silver per ton. Underlying this is a sulfide zone with 17.7 million tons of ore averaging 0.13 ounce gold and 1.12 ounce silver per ton, 2.19% zinc, and 0.25% copper.

El Salvador.—San Sebastian Gold Mines, Inc., planned to increase production at its gold property in the eastern part of El Salvador from 400 to 1,000 ounces per month. Known reserves were reported at 300,000 tons averaging 0.35 ounce per ton; total reserves were placed at 7 million tons grading 0.05 to 0.10 ounce per ton.

Fiji.—Despite a nearly 14% decline in production, Fiji's gold mining was more profitable than in 1973 owing to higher gold prices. Most high-grade ores were exhausted but lower grade ores were estimated adequate for an additional 25 years at existing rates of extraction.

France.—Techniques for treating arsenical gold ores were improved at the Salsigne mine of Mines et Produits Chimiques de Salsigne in the Carcassonne region of central France, increasing ore reserves as a result. Plans to sink a new shaft to a depth of 1,260 feet initially, extending it to 2,200 feet eventually were reported. In 1973, the mine yielded 49,675 ounces of gold, 161,146 ounces of silver, 338 tons of copper, 38 tons of bismuth, 6,630 tons of arsenious trioxide, and 20,000 tons of sulfuric acid. Silver Eureka Corp. (Canada) controls the French company.

Germany, West.—During the first half of 1974, 225,000 ounces of gold was imported from the U.S.S.R. This compared with 289,000 ounces from this source during the first half of 1973.

Honduras.—Alianza Industrial S.A. obtained an option on the Tatumbla gold property and planned test work and rehabilitation. An estimated 225,000 tons grading 0.2 ounce of gold and 0.5 ounce of silver per ton was available to open pit mining.

India.—Gold smuggling into India was expected to decline to about 1 million ounces in 1974 after reaching an estimated 4.5 million ounces in 1972 and 2.5 million ounces in 1973. Bharat Gold Mines Ltd. (Government-owned) operated mines in the Kolar goldfields, while the Karnataka State-owned Hutti Gold Mines Co., Ltd. operated mines in the Hutti area. With the assistance of the Geological Survey of India, Bharat Gold Mines accelerated underground exploration at its Champion Reef and Nundydroog mines and reportedly located new near-surface gold in sulfide ores in the western part of the old Kolar field. Exploration was also underway at Ramgiri, Andhra Pradesh, and at Mamandur, Tamil Nadu. In 1973, Bharat Gold Mines had operated at a loss, with total production costs averaging $156.53 per troy ounce on an output of 57,163 ounces of gold. Losses were partially offset by a $5.3 million subsidy. India's total 1973 ore output was 620,012 short tons averaging 0.17 ounce of gold per ton. Combined ore reserves at Kolar and Hutti remained at 4.6 million tons averaging 0.25 ounce per ton.

Indonesia.—Mining permits were issued for primary gold deposits in the Bogor and Sukabumi areas of West Java and the Solak area of West Sumatra; permits were also issued for placer gold and associated minerals in the Meulaboh area of Aceh and in West, Middle, and East Kalimantan. Most of Indonesia's gold production continued to come from the Tjikotok and Tjirotan mines in West Java.

Japan.—Sumitomo Shoji Kaisha, Ltd. estimated Japanese gold consumption in fiscal year 1973–74 (ending April 1974) at 4.2 million ounces, including 0.8 million ounces going to "private hoarding." Of the remaining 3.4 million ounces, jewelry and industrial art works required, 44%; communication and gilding, 22%; dental and medical uses, 14%; decorations and insignias, 9%; timepieces, 3%; and other uses, 8%. The supply came from imports, 71%; primary production, 26%; and secondary sources, 3%. During the calendar year 1973, imports totaled 3.85 million ounces, 56% from the United Kingdom, 40% from Switzerland, and 4% from eight other countries. Imports were 1.13 million ounces in the first 5 months of 1974.

Mexico.—Silver-gold deposits were under development by Lacanex Mining Corp. (Canada) in the Guanajuato area of Mexico. A silver-gold property in Taviche, Mexico, was being brought into production at a 200-ton-per-day milling rate by several Canadian firms.

Nicaragua.—Rosario Resources Corp. rehabilitated the shaft at the Siuna mine, purchased from La Luz Mines, Ltd., and installed new equipment. Total proven and probable ore reserves at yearend were reported at 10.2 million tons averaging 0.073 ounce of gold per ton. The mine has a 2,000-ton-per-day mill, unused since 1968.

Papua New Guinea.—New Guinea Goldfields, Ltd. operated its Golden Ridges mill at 7,000 tons per month in early 1974, yielding 312 fine ounces of gold and 254 ounces of silver. Production was down owing to a metallurgical problem.

Peru.—Peru sold about 21,000 ounces of gold bullion in May 1974 through the Bank of Nova Scotia (Canada). Most of the country's gold continued to come from the Cerro de Pasco smelter at La Oroya but increasing amounts came from small-scale placer mining with encouragement of the Banco Minero del Peru.

Philippines.—Benguet Consolidated Inc. produced about 135,000 ounces of gold in 1974 compared with 180,000 ounces in 1973. Production was from two mines, the Acupan and Antamok, in Mountain Province, 150 miles north of Manila on Luzon. During the year there was a substantial increase in ore reserves at the Acupan mine; plans for block-caving were considered for the Antamok mine as part of a 3-year development program. Company reserves were about 2 million tons of ore at yearend. A gold placer mining venture was planned by Golden River Mining Corp. in Paracale, Camarines Norte, where it was estimated 2 million yards of material contained 13,000 ounces of 850 fine gold. Also, in the same area Metals Exploration N.L. drilled the Longes gold lode and estimated reserves at 0.6 million tons averaging about 0.8 ounce per ton.

Rhodesia, Southern.—The Rhodesian Mine Ministry was reportedly expecting an additional 74 gold mines to come into production in 1974 following the establishment of 87 new mines in 1973. Presumably, these were relatively small operations.

Sierra Leone.—The Government granted placer gold mining licenses to 9 Sierra Leoneans and declared 17 chiefdoms of the country as gold mining areas subject to the Alluvial Gold Mining Regulations. Districts covered were the Koinadugu, Tonkolili, Bombali, Kailahun, and Kono. A small quantity of gold was produced and exported.

South Africa, Republic of.—South African gold production fell for the fourth consecutive year, declining 11% to 24.4 million ounces. The tonnage of ore milled in 1974 was down less than 1% to 73 million tons; however, the average grade of ore milled declined 11% to 10.19 grams per metric ton (0.30 ounce per short ton). Labor problems intensified during the year and employment was estimated 15% to 20% below normal by yearend. Total underground labor was down to about 274,000. Randfontein Estates Gold Mining Co. Ltd. reopened its old No. 32 shaft and produced from its No. 1 Cooke section shaft beginning in 1974. Capacity in 1975 was expected at 70,000 tons per month and was to double late in 1977 when the No. 2 shaft was to be completed. Only 4 out of 42 active mines increased production tonnages in 1974; the largest increases were at the Western Areas mine (up 21%) and the East Driefontein mine (up 15%).

The West Driefontein mine remained the largest gold producer in the world, with output of 2.28 million ounces from 3.05 million tons of ore milled averaging 0.748 ounce per ton. In tonnage extracted and milled the Vaal Reefs mine was larger, however, with 6.49 million tons yielding 2.08 million ounces from ores averaging 0.321 ounce per ton. The deepest mine remained the Western Deep Levels at more than 12,000 feet to bottom. Mines with over 1 million ounces production in 1974 were as follows: West Driefontein, Vaal Reefs, Western Deep Levels, President Brand, Western Holdings, Free State Geduld, and Hartebeestfontein. Significant amounts of uranium were also produced with gold at eight mines as follows: Vaal Reefs, Buffelsfontein, Harmony, Hartebeestfontein, West Driefontein, Blyvooruitzicht, Western Deep Levels, and West Rand Consolidated.

Exploration activities were high in the South African gold areas during the year. Two new mines were under development, one at Buffelsdoorn by Anglo American Corp. of South Africa Ltd., and the other at Deelkraal, east of Buffelsdoorn, by Gold Fields of South Africa Ltd. Each property was expected to require on the order of $150 million to start production. Promising exploration results were reported near the Jeanette mine in the Orange Free State and various locations on the Witwatersrand. Anglo American Corp. announced plans to spend $90 million on improved housing for 120,000 African miners on the company payroll. During the fiscal year ending May 31, 1974, tax payments to the Government by South African gold mines were $330 million, nearly double those of fiscal 1973 and lease payments nearly doubled to $156 million. Bids by several firms to acquire Union Corp. were unsuccessful.

Surinam.—Placer Development Ltd. (Canada) and the Surinam Government signed a joint venture agreement in June to explore and mine gold deposits near the town of Brokopondo. Most past production has been in the areas of Lawa and Tapanahony.

U.S.S.R.—In a study by Consolidated Gold Fields Ltd., Soviet gold production was estimated to have doubled in the past 12 years and was expected, according to Soviet plans, to approximate 14 million ounces in 1975. Byproduct gold comprised 11% of production. Main gold producing areas included the following: Severovostok, 24%; Yakut, 15%; Zabaikal, 7%; Zapsib, 6%; Armenia, 5%; Uzbek, 5%; Lena, 4%; Amur, 3%; Kazak, 2%; Ural 2%; and Yenisey, Altai, Primorsky, Tadzhik, Kirgiz, and others, 27%. Individual producers in unspecified areas accounted for 9% of the total 1975 production. Expected production from gold ores was 5.7 million ounces in 1975, with about 1.4 million ounces from three large strip operations (NizhnyKuranakh, Muruntau, and Bakyrchik), 3.1 million ounces from 17 principal underground mines (including Zod, Darasun, Taseev, Berezov, Kachkanar, Sovetskoye, and Matrasov), and the remainder from a number of smaller mines. Milling practices mentioned generally included flotation, cyanidation, activated carbon extraction, ion extraction, and a "sorption" process. Placer mining should account for nearly 50% of total gold output in 1975, mainly from the Siberian area of the country.

TECHNOLOGY

Studies were conducted in Bureau of Mines laboratories at Reno, Nev., and Salt Lake City, Utah, on two main approaches to gold recovery from low grade ores—electro-oxidation and heap leaching.

At Reno, studies were mainly directed at an electro-oxidation process in which a brine solution of the ore pulp is subjected to electrolysis causing a hypochlorite to form which oxidizes organic compounds that can interfere with cyanide gold extraction. A procedure was developed in which gold extraction from carbonaceous ores was improved from about 30% to the 87% to 95% range, with electric power consumption of 40 to 60 kilowatt-hours and salt consumption of 20 to 60 pounds per ton of ore. Late in the year, onsite studies were conducted at the Carlin gold mine in Nevada to determine if electro-oxidation might be more economical than the existing chlorine gas treatment on the carbonaceous portion of the Carlin ores. Comparative data showed that electrical power costs to achieve similar results would be only 22% to 33% of costs for chlorination. Other studies showed that the 10% brine solution required would not be deleterious to the succeeding cyanidation circuits. Laboratory studies were conducted on electrode wear in a 30% pulp slurry with 4.5% sodium chloride to determine typical replacement costs. Also at Reno, a test unit was constructed to strip and electrowin gold and silver values from activated carbon using ethanol and methanol in an alkaline solution. Recycling of carbon after ethanol stripping was improved by dewatering in a basket centrifuge followed by two-stage washing with 2% nitric acid solution. The process was submitted for patent.

At Salt Lake City, heap-leaching results were studied using samples from various Western gold properties, and methods were found to improve activated carbon gold extraction. An improved cell was developed for electrowinning gold from carbon strip solutions. Elevated-temperature, pressure-stripping experiments continued for accelerating removal of gold from the carbon. The various uses of activated carbon in gold extraction systems were reviewed and relative cost factors for three processes were compared.[7] Heap leaching was estimated to require 23% of the capital and 30% to 44% of the operating costs of a traditional cyanidation plant with a 2,500-ton-per-day capacity. A factor in the comparison was a somewhat lower gold recovery rate, in general, by heap leaching.

The use of a carbon-in-pulp gold cyanidation technique at the Homestake gold mine, South Dakota, was described.[8] The treatment was used on the slime fraction of the mill product and has been successful in lowering costs and improving gold recovery. Carbon was reactivated by heating to 1,100° F in a small gas-fired rotary kiln in the absence of air for a period of one-half hour.

A process was patented using chlorine gas to oxidize carbonaceous material in sedimentary gold ore before cyanidation at the Carlin mill in Nevada.[9] Several techniques of increasing recoveries of gold from refractory ores were patented involving treatment with a gaseous stream of chlorine at an elevated temperature in the presence of certain compounds acting as promoters.[10] A speedup in gold and silver cyanidation was realized by addition of stabilized solutions of peroxides in another process.[11] The resulting electrolyte solution was said to be suitable for direct electrodeposition. In one test, 99% of the gold from the treated ore was extracted in 50 minutes.

A solvent extraction method for gold was used on a production scale by a Canadian refiner, promising more efficient extraction from aqua regia solutions.[12] Dibutyl Carbitol was the extracting solvent. An increased yield of pure metal was claimed compared with extraction by ferrous sulfate and electolysis. Gold, silver, and copper values in a cyanide solution were concentrated by a semipermeable membrane of selected polymers in a new process utilizing reverse osmosis.[13]

In development of gold exploration technology, a report was published describing studies of sampling methods for placer gravels in the Sierra Nevada foothills of northern California.[14] Tests were made of a truck-mounted rotary drill, a vibratory drill, and a bucket drill to determine characteristics and reliability of each. For onsite control of the mining grade of ore at the Gold Acres gold property in Nevada, a mobile laboratory was used employing an atomic absorption spectrophotometer unit.[15] Samples were taken and analyzed close to the working face at the rate of about 50 per day.

Mining technology improvements in the Republic of South Africa were the object of a new research program initiated by the Chamber of Mines of South Africa.[16] A 10-year program was planned to increase gold mining productivity. A mining system new to the South African goldfields—sublevel stoping—was used in an area of the Lorraine gold mine where a number of reef bands merged to form a zone about 70 feet thick.[17] A new design for cement and timber packs used in stope support in a South African mine was said to result in savings of material and labor.[18] A high-thrust raise borer was used to drill 9-foot-diameter holes over 300 feet long in quartzite at the Vaal Reefs South gold mine in South Africa.[19]

Depositional controls for gold deposits in the Black Hills region of South Dakota were discussed and suggestions given as to where new discoveries might be made.[20] Three main controls were recognized: Cross folds; the Homestake formation; and proximity to the "garnet isograd", a zone of metamorphic change characterized by increased garnet content. Favorable target areas were said to include the area north of Lead, the Portland and Ruby Basin region, and the Rockerville area. A study of lead isotopes in ores of the Homestake gold mine, South Dakota, showed that the deposit was Precambrian age and that Tertiary veinlets in the Precambrian host rocks and Tertiary intrusive rocks were derived from Precambrian rocks.[21]

Results of a geochemical study for gold in Precambrian and Paleozoic sedimentary rocks in the Great Lakes region suggested that if fossil gold placers were present they might be in the basal Paleozoic clastic rocks near James Bay, Canada, north of the Great Lakes.[22] Several reports were published on past gold placer mining; one covered deposits in Colorado[23] and another described activities in the Southwestern United States.[24]

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Unless otherwise indicated, production is on the basis of mine output.

[2] Gold is also produced in Bulgaria, Czechoslovakia, Spain, and probably in small quantities in Argentina, Burma, East Germany, Hungary, Thailand, and several other countries. However, available data are insufficient to make reliable output estimates. Data are lacking on clandestine activities.

[3] Revised to zero.

[4] Partial figure representing sales by medium mines to the Central Bank, excludes a relatively small quantity mined as byproduct of COMIBOL operations.

[5] Purchased by the Bank of Monrovia.

[6] Refinery production for Japan was as follows: 1972—[r] 846,239 ounces; 1973—1,052,775 ounces; 1974—1,123,474 ounces.

[7] Recoverable gold from copper ore; total content of copper ore was as follows in troy ounces: 1973—1,057,782; 1974—1,094,082.

Graphite

By W. Timothy Adams [1]

Crystalline natural-graphite flake remained in short supply throughout 1974 and the market continued tight throughout the year. Prices of this imported flake rose approximately 20% compared with 1973 prices. The principal cause of the shortage was the continued lack of production in the Malagasy Republic, the main source of large-flake crystalline graphite. However, supplies of Mexican amorphous graphite remained sufficient, and attempts to substitute it for the scarce crystalline flake appear to have been moderately successful.

Imports of natural crystalline and amorphous graphite were up 5%, crystalline flake gained approximately 1,000 tons. Exports of natural graphite increased 53% to 12,189 tons.

The difficult supply problem was maintained as demand continued strong for the fourth consecutive year.

The manufactured-graphite industry had another good year as production increased 8%. Production of electrodes decreased slightly, whereas production of crucibles and vessels increased sharply. Major expansions of facilities were announced by several producers.

Table 1.—Salient natural graphite statistics

	1970	1971	1972	1973	1974

[e] Estimate. [r] Revised.

[1] Estimated demand has been substituted for the consumption survey results previously published, since the latter are incomplete. A figure comparable to the previous series appears as the total of table 4.

[2] Includes some manufactured graphite.

Legislation and Government Programs.—As part of the effort to reduce strategic stockpile inventories, more than 50% of the natural graphite in the stockpile was declared surplus by the General Services Administration (GSA). Although GSA determines the requirements for strategic materials, congressional authorization is still required for disposal. Of the three types of stockpiled graphite, about 50% of the Malagasy and Sri Lanka types and all of the other types were placed on the surplus list. However, congressional authorization for their disposal has not been obtained, and no sales were made. All stockpiled graphite that was previously authorized for disposal was sold and shipped.

DOMESTIC PRODUCTION

In 1974, natural-graphite production in the United States was again from a single location, the Southwestern Graphite Co. mine near Burnet, Tex. Shipments from the mine were slightly higher than in 1973, and continued to account for only a small portion of the domestic supply. Other graphite deposits in Alabama, California, Idaho, New York, Texas, and Virginia continued to arouse the interest of investigators contemplating the development or redevelopment of additional mines, but no mine openings occurred by yearend.

Production of manufactured graphite continued to increase in 1974. Output of 322,513 tons was up 5% from the 306,212 tons produced in 1973. Total value of production increased 27% to $280.1 million from $220.0 million in 1973. The use of powder and scrap material increased from 25,722 tons valued at $3.7 million in 1973 to 35,390 tons valued at $13.5 million in 1974.

Metallurgical use of manufactured graphite showed a small advance. Although electrode production decreased, the tonnage used in crucibles and vessels increased sharply as the metallurgical industry continued its changeover to processes such as continuous casting, which make use of increased amounts of graphite. Unmachined shapes also continued to advance. Graphite-fiber composites have gained consumer acceptance in the leisure-products and sporting-goods industries. As a result, production costs of graphite fibers have dropped substantially and are expected to continue to decrease. The development of hybrid composites, such as graphite-polyimide and Kevlar-graphite-epoxy, provided a combination of properties that overcome many of the deficiencies of earlier composites such as graphite-epoxy and graphite-polyester. With the hybrid materials available in broad-woven form and with better fabrication techniques, assemblies became less labor intensive. The aerospace industry was quick to take advantage of these new developments and used composite assemblies in the B–1 bomber and F–16 and YF–17 fighters. The Teledyne Ryan Aeronautical YQM–98A remotely piloted aircraft used more than 100 hybrid composite assemblies including primary-structure, outer-wing panels. The Wendecker Eagle private aircraft was built using all-composite construction. Potential industrial applications generated interest, since the composites are lightweight and have acoustical and vibration dampening, and heat stability characteristics.

Manufactured graphite was produced at 25 plants in 1974, and some additional production for inhouse use was likely. The following is a list of principal producers in 1974.

Company	Plant location
Airco, Inc., Speer Div	Niagara Falls, N.Y.
Do	Punxsutawney, Pa.
Do	St. Marys, Pa.
Avco Corp., Avco Systems Div.	Lowell, Mass.
The Carborundum Co., Graphite Products Div.	Hickman, Ky.
Do	Sanborn, N.Y.
Celanese Corp., Celanese Research Lab.	Summit, N.J.
Fiber Materials, Inc	Graniteville, Mass.
Great Lakes Carbon Corp.	Rosamond, Calif.
Do	Niagara Falls, N.Y.
Do	Morganton, N.C.
Hercules, Inc	Bacchus, Utah.
HITCO	Gardena, Calif.
Morganite Modmor, Inc.	Costa Mesa, Calif.
Ohio Carbon Co	Cleveland, Ohio.
Pfizer, Inc., Minerals Pigments and Metals Div.	Easton, Pa.
Poco Graphite, Inc	Decatur, Tex.
Polycarbon, Inc	North Hollywood, Calif.
Stackpole Carbon Co	Lowell, Mass.
Do	St. Marys, Pa.
Super Temp Co	Santa Fe Springs, Calif.
Union Carbide Corp	Niagara Falls, N.Y.
Do	Yabucoa, P.R.
Do	Columbia, Tenn.
Wickes Engineered Materials.	Saginaw, Mich.

An expansion of the graphite fiber production facility at Bacchus, Utah, was announced by Hercules, Inc. New equipment will enable doubling the plant output.[2]

Table 3.—Production of manufactured graphite in the United States in 1974, by use

Use	Quantity (short tons)	Value (thousands)
Manufactured graphite products:		
Electrodes	209,466	$176,060
Crucibles and vessels	19,655	22,519
Motor brushes and machine shapes	2,592	7,250

Cloth and fibers	65	W
Other	[1] 70,980	[2] 74,820
Total	322,513	280,149
Synthetic graphite powder and scrap	35,390	13,524
Grand total	357,903	293,673

W Withheld to avoid disclosing individual company confidential data; included with "Other."

[1] Includes anodes, refractories, high-modulus fibers, and other minor products.

[2] Includes anodes, unmachined shapes, cloth, fiber, high-modulus fibers, and other minor products.

Union Carbide Corp. selected Clarkesville, Tenn., as the site of its major new graphite-electrode plant. The initial unit is scheduled to go into operation in 1977.[3] Union Carbide had previously announced a 20% expansion of capacity at its Columbia, Tenn., and Yabucoa, P.R., plants. Initial production from the expanded facilities was scheduled for early 1975.[4]

Great Lakes Carbon Corp. announced a 50% increase in graphite-electrode-manufacturing capacity at plants in Niagara Falls, N.Y., Morganton, N.C., and Rosamond, Calif.[5] Airco Speer Carbon Graphite Div. of Airco Inc. announced a 25% increase in overall production capacity at the Niagara Falls, N.Y., and St. Marys, Pa., plants.[6]

CONSUMPTION AND USES

Demand for natural graphite remained strong in 1974. Consumption in steel mills increased sharply, but use in foundries dropped as activity in this area reflected the downturn in business. Use of graphite in brake and clutch linings and powdered metals also declined. Consumption in the manufacture of crucibles and associated products increased, reflecting efforts by that industry to decrease its dependence on Malagasy flake. Exports increased to 12,000 tons. Total consumption of natural graphite was considerably greater than that shown in table 4, which reports only the results from known graphite consumers. Total graphite consumption is estimated to have been approximately 95,000 tons in 1974.

[4] Includes ammunition, packings, and seed coating.

[5] Includes paints and polishes, antiknock and other compounds, drilling mud, electrical and electronic products, insulation, magnetic tape, small packages, and miscellaneous and proprietary uses.

PRICES

Graphite prices rose sharply again in 1974 as the world shortage continued. Domestic prices responded to the higher cost of foreign graphite since most of the U.S. supply is imported. Prices of all the principal types of imported crystalline-flake graphite were significantly above their 1973 levels; increases ranged from 11% to 40%. Malagasy crystalline flake, the most important type of flake graphite, rose an average of 17% in price during the year. Sri Lanka amorphous lump and chip increased an average of 39%. Mexican graphite, the principal amorphous type imported, increased 30% in price.

Price quotations represent a range of prices. Actual prices are often on a negotiated basis between the buyer and the seller. One source of information for imported graphite is the average value per ton of the different classes of imports, which can be computed from table 6; however, it should be kept in mind that these represent mainly shipments of unprocessed graphite.

No published source of domestic price quotations has been found that reflects the increases that have taken place in the past several years. Price information can be obtained from the companies that produce and import natural graphite. The following tabulation shows representative prices of several types of imported graphite as of December 1974 published in the Engineering and Mining Journal. All prices are f.o.b. the foreign port or border station and have been converted from metric tons.

	Per short ton	
	1972	1973
Flake and crystalline graphite, bags:		
Germany, West	$204–$1,179	$234–$1,495
Malagasy Republic	159–476	188–558
Norway	109–181	150–247
Sri Lanka	181–318	248–446
Amorphous, nonflake cryptocrystalline graphite (80% to 85% carbon):		
Korea, Republic of (bags)	27	30
Mexico (bulk)	22	28.50

FOREIGN TRADE

A rise in exports of natural graphite occurred in 1974, continuing the upward trend begun in 1972. Exports gained 53% to 12,189 tons compared with 7,953 tons in 1973. The principal buyer was Canada, which took 4,277 tons. Other countries purchasing several hundred tons apiece were; Australia, Brazil, Italy, Japan, Mexico and the United Kingdom. Graphite was also exported to 29 additional countries.

Imports of natural graphite increased 3.9%, but the rise did not signal an end to the graphite-supply problem. Imports of amorphous graphite from Mexico were virtually the same as for 1973. Imports of crystalline flake from the Malagasy Republic increased 646 tons to 3,378 tons in 1974, which was 2,500 tons short of the 1972 figure. The figures appear to indicate a continued effort by industry to substitute the more plentiful amorphous graphite in products normally requiring crystalline flake, with a consequent increase in the quantities needed. The continued search by industry for crystalline flake resulted in imports of 548 tons from the U.S.S.R. and 187 tons from Malaysia, both new sources for this material. However, these amounts are insignificant compared with the shortfall in Malagasy flake.

Table 5.—U.S. exports of natural graphite,[1] by country

WORLD REVIEW

World production of natural graphite increased in 1974, but the gain was not sufficient to keep pace with the growing international market. Production of amorphous graphite in Mexico and the Republic of Korea continued to be adequate. A critical shortage of Malagasy crystalline flake still remained. As a result, the overall situation in world markets changed little from that in 1972 and 1973.

India.—Geological Survey of India announced that a deposit of high-grade graphite estimated at 330,000 short tons had been found in the Idikki District.[7]

Malagasy Republic.—The continued tense political climate in the country as a whole, and particularly in the graphite-producing region and Tamatave, continued to affect production. Cyclone damage to the railroad and road networks continued to hamper transport of mined materials.

Norway.—A/S Skaland Grafitverk completed a new processing plant that gives a higher grade product and increases production.

Sri Lanka.—The State Graphite Corp. conducted feasibility studies on a new mine site at Rangala in the Yatiuantola district. Results indicated the mine can be worked on a commercial basis. Preliminary work was completed on another new mine at Ragedra in the Dodangaslanda district. A pilot plant was established in collaboration with the Ceylon Institute of Scientific and Industrial Research to investigate the beneficiation of lower grades of graphite. The Corporation negotiated with a U.S. company to set up a plant for manufacturing petroleum-based semicolloidal graphite lubricants, primarily for the Southeast Asia market.[8]

[3] Production of A/S Skaland Grafitverk only.

[4] Exports.

TECHNOLOGY

Although research efforts continued to be concentrated on manufactured graphite and its uses in 1974, several new developments occurred pertaining either to natural graphite or both natural and manufactured graphite.

Graphite fluoride continued to be studied. Careful temperature control in the range

627±3° C resulted in the synthesis of poly (carbon monofluoride).[9] The white compound is stable in air to 600° C. Studies showed the compound is a superior solid lubricant under heavy loads, high temperatures, in oxidizing atmospheres, and under other extreme conditions.[10] Other work demonstrated a high potential for carbon monofluoride as a cathode material in high-energy batteries.[11]

A series of patents assigned to the Sagami Chemical Research Center (Japan) were issued on graphite-complex catalysts for chemical synthesis. The C_8K and the $C_{24}K$ complexes have a remarkable ability to absorb hydrogen, nitrogen, and methane. The observations suggest a parallel to the catalytic ammonia synthesis accomplished with graphite-$FeCl_3$-K complexes. Activity for hydrocarbon synthesis from CO and H_2 (producer gas) is also described. In addition, C_8K catalyzes the room-temperature addition of primary and secondary amines to dienes to give alkenylamines. Acetic acid was synthesized in high yield from methanol and CO over a graphite-$RhCl_3$-I_2 complex.[12]

The use of graphite as an additive in powder metallurgy assumed increasing importance when it appeared the automotive industry would make increased use of this fabrication technique. In another application, graphite not only supplies the carbon, but also functions as a lubricant in steel-alloy powders. Both of these applications require a crystalline flake material and should further aggravate the already tight supply of this material. Graphite use as a carbon additive is also increasing because of the growing use of electric furnaces by the steel industry. Graphite is favored over coke in this and other processes because of its lower sulfur content.

Refractory use of natural graphite increased, spurred by its cost advantage over substitute materials, and was more readily available than energy-intensive materials. Work on graphite continued, to increase its oxidation resistance and ease of application, and improve its refractory characteristics.[13]

Another area of major growth for natural graphite appeared to be in lubricants. Design engineers evaluated the properties of graphite and specified increased prelubrication for fabricating steel, forging, die casting, and powder metallurgy. Lengthened tool and die life and increased production were realized as well. An additional impetus to convert to water-based graphite lubricants was decreased air-pollution control problems caused by fuming of petroleum-based lubricants. The swing should be aided by the increasing costs of petroleum-derived lubricants. Graphite was also used as a lubricant in continuous casting, and its use in this application will grow as the number of continuous casting installations increase.

Rammed graphite molds (replacing sand molds) made titanium casting commercially feasible. The graphite molds gave excellent dimensional accuracy, and increased metal utilization from 17% to 58%.[14]

Graphite filament use continued to grow as increased numbers of aircraft secondary structures were designed to utilize the properties of the material. Applications continued to spread beyond the aerospace field. Sporting goods account for the major commercial use of graphite filament in such items as golf clubs, tennis rackets, fishing rods, and bicycle frames. Increased production and concurrent lower prices began to focus attention on industrial applications.

Development of metal-graphite composites continued. Based on earlier work done on liquid infiltration of aluminum-graphite composites, a similar approach to the fabrication of copper-graphite composites appreciably improved their physical characteristics. For example, copper-graphite was expected to maintain its room-temperature properties at temperatures near the melting point of copper. At higher temperatures, the use of beryllium-copper alloy was contemplated.

Gypsum

By Avery H. Reed [1]

Activity in the gypsum industry declined in 1974 following the general depression in the building industries. Output of crude gypsum declined 12% to 12 million tons. Production of calcined gypsum declined 13% to 11 million tons. Sales of prefabricated products declined 14%, to 11.9 million tons. Imports decreased 3% to 7.4 million tons. Total value of gypsum products sold or used decreased 2% to $623 million.

[r] Revised.
[1] Each mine, calcining plant, or combination mine and plant is counted as one establishment.
[2] Excludes byproduct gypsum.

DOMESTIC PRODUCTION

Forty-four companies mined crude gypsum at 75 mines in 22 States. Of these, 62 were open pit and 13 were underground mines. Output of crude gypsum declined 12%, to 12 million tons. Leading States were California, Michigan, Iowa, Texas, and Oklahoma. These 5 States, with 31 mines, accounted for 60% of the total domestic production.

Leading companies were United States Gypsum Co. (13 mines); National Gypsum Co. (8 mines); Georgia-Pacific Corp. (7 mines); H.M. Holloway Inc. (1 mine); and The Flintkote Co. (3 mines). These 5 companies, operating 32 mines, produced 72% of the total crude gypsum.

Leading individual mines were U.S. Gypsum's Plaster City mine in Imperial County, Calif., H.M. Holloway's Lost Hills mine in Kern County, Calif., National Gypsum's Tawas mine in Iosco County, Mich., and U.S. Gypsum's Alabaster mine in Iosco County, Mich. These four mines accounted for 21% of the national total.

Thirteen companies calcined gypsum at 77 plants in 29 States. Output declined 13% to 11 million tons. Leading States were California, Texas, New York, and Iowa. These 4 States, with 26 plants, accounted for 37% of the total production.

---

[1] Supervisory physical scientist, Division of Nonmetallic Minerals.

Leading companies were U.S. Gypsum Co. (23 plants); National Gypsum Co. (19 plants); Georgia-Pacific Corp. (10 plants); The Flintkote Co. (6 plants); and The Celotex Corp. (5 plants). These 5 companies, operating 63 plants, accounted for 85% of the total domestic output of calcined gypsum.

Leading individual plants were U.S. Gypsum's Plaster City plant in Imperial County, Calif.; Weyerhaeuser's Briar plant in Howard County, Ark.; U.S. Gypsum's Shoals plant in Martin County, Ind.; U.S. Gypsum's Stony Point plant in Rockland County, N.Y.; Georgia-Pacific's Acme plant in Hardeman County, Tex.; U.S. Gypsum's Fort Dodge plant in Webster County, Iowa; U.S. Gypsum's Jacksonville plant in Duval County, Fla.; National Gypsum's Savannah plant in Chatham County, Ga.; National Gypsum's Shoals plant in Martin County, Ind.; and U.S. Gypsum's Sweetwater plant in Nolan County, Tex. These 10 plants accounted for 25% of the national total.

In California, Occidental Petroleum Corp., Valley Nitrogen Producers Inc., and Collier Carbon & Chemical Corp. sold 463,000 tons of byproduct gypsum valued at $4,302,000 for use in agriculture.

The United States is the world's leading producer of gypsum, accounting for 18% of the total world output.

CONSUMPTION AND USES

Apparent consumption of crude gypsum (production plus imports minus exports) decreased 8% to 19.4 million tons. Imports were 38% of consumption. Apparent consumption of calcined gypsum declined 13% to 11.0 million tons.

Stocks of crude gypsum at mines and plants at yearend were 3.6 million tons. Of this, 2.3 million tons or 65% was at plants in coastal States.

Of the total gypsum products sold or used, 5.9 million tons (31%) was sold uncalcined. Of the total uncalcined gypsum, 4.1 million tons (69%) was used for portland cement and 1.7 million tons (29%) was used in agriculture. The leading sales regions for gypsum used in cement were the West South-Central, Middle Atlantic, and East North-Central, which accounted for 51% of the total. For agricultural gypsum, the Pacific sales region accounted for 85% of the total.

Of the total calcined gypsum, 93% was used for prefabricated products and 7% for plasters. Of the prefabricated products, 71% was regular wallboard, 22% was fire-resistant Type X wallboard, and only 2% was lath. Of the regular gypsumboard, 86% was of the ½-inch type. The leading sales regions for prefabricated products were the South Atlantic, the East North-Central, and the Pacific, which accounted for 50% of the total. For plaster, the East North-Central, South Atlantic, and Middle Atlantic accounted for 62% of the total.

PRICES

The value of crude gypsum increased from $4.18 per ton in 1973 to $4.41 in 1974. The value of calcined gypsum increased from $16.31 to $18.71. The average value of byproduct gypsum sold was $9.29 per ton.

The average value of gypsum products increased from $30.67 in 1973 to $33.33 per ton in 1974. Prefabricated products were valued at $45.94, industrial plasters at $44.80, building plasters at $37.63, and uncalcined products at $6.62 per ton.

Quoted prices for gypsum are published monthly in the Engineering News-Record. Prices at yearend showed a wide range, based on delivered prices. Regular ½-inch wallboard prices ranged from $40 per thousand square feet at Dallas to $93 at Chicago. Prices for plaster ranged from $52 per ton at St. Louis to $71.25 at Boston.

FOREIGN TRADE

The gypsum industry depends on imports. In 1974, 38% of the crude gypsum supply was imported. Imports were from Canada (77%), Mexico (16%), Jamaica, Dominican Republic, Morocco, the United Kingdom, Venezuela, and Italy. Imports decreased 3% to 7.4 million tons. Exports of crude gypsum were 14,210 tons.

WORLD REVIEW

Canada.—Canada was the second leading producer of crude gypsum, accounting for 12% of the world total. About three-fourths of Canadian gypsum is exported to the United States, mainly from Nova Scotia. This exported gypsum is mined by Canadian subsidiaries of United States gypsum companies.

The Flintkote Co. of Canada Ltd. mined gypsum in Newfoundland. Active producers in Nova Scotia were Little Narrows Gypsum Co. Ltd.; Georgia-Pacific Corp.; Fundy Gypsum Co. Ltd.; National Gypsum Co. Can.; and Domtar Construction Materials Ltd. Canadian Gypsum Co. Ltd. and Canada Cement Lafarge Ltd. mined gypsum in New Brunswick. Canadian Gypsum Co. Ltd. and Domtar Construction Materials Ltd. operated underground gypsum mines in Ontario. Westroc Industries Ltd. and Domtar Construction Materials Ltd. mined gypsum in Manitoba. Western Gypsum Mines Ltd. mined gypsum in British Columbia.

Egypt, Arab Republic of.—Gypsum deposits recently discovered at Gharbanian were estimated to contain 12 million tons, a 30-year supply for Egypt.

France.—France was the third leading gypsum producing country, with 10% of world production.

Spain.—Spain ranked fifth in world gypsum production with 7% of the total.

U.S.S.R.—The U.S.S.R. produced 7% of the world's gypsum and ranked fourth.

[4] Net exports.

TECHNOLOGY

Planned developments to remove sulfur from stack gases by using lime or limestone could result in the accumulation of large quantities of impure byproduct gypsum. The problems of disposal or potential uses of this material are being studied.

Helium

By Ronald F. Balazik [1]

Sales of high purity helium (99.995% purity) in the United States during 1974 totaled 539 million cubic feet, an increase of over 8%.[2] The Bureau of Mines sold 31% of this total, and private industry sales accounted for the remaining amount. High purity helium exports, all by private industry, totaled 160 million cubic feet during 1974. The Bureau of Mines f.o.b. plant price for high purity helium during 1974 remained at $35 per thousand cubic feet, but private industry prices rose from an average of $21 to an average of $23 per thousand cubic feet.

On May 3, 1974, the Supreme Court declined to review the decision of the U.S. Court of Appeals under which the U.S. Department of the Interior terminated its helium conservation contracts in late 1973 with the National Helium Corp., Phillips Petroleum Co., and Cities Service Helex, Inc. Final settlement by the three contractors of claims arising from the termination of the contracts is still pending.

On December 3, 1974, a trial judge of the U.S. Court of Claims ruled that a fourth contractor, Northern Helex Co., was entitled to $78 million in damages because the Government had breached its helium purchase contract with the company. This ruling is subject to review by the full Court of Claims and possible appeal to the U.S. Supreme Court.

A bill to authorize the Secretary of the Interior to conserve and store helium was introduced in the House of Representatives, U.S. Congress, on June 6, 1974. It directed the Secretary of the Interior to store and redeliver helium produced in private helium extraction plants at no expense to the producer. The bill was not enacted into law.

DOMESTIC PRODUCTION

A total of 11 plants in the United States had the capability to extract helium during 1974. Nine of the plants were owned by private industry, and the remaining two were owned by the Federal Government and operated by the Bureau of Mines. An additional plant was being constructed near Redrock, N. Mex., by Western Helium Co. to replace its dismantled plant near Navajo, Ariz.

During 1974, total helium extracted from natural gas declined about 72% to 883 million cubic feet following the termination of helium conservation storage contracts in December 1973. However, high purity helium output increased 8% to 699 million cubic feet. Approximately 21% of the total helium extracted was crude helium[3] and 79% was high purity helium produced for sale. The Bureau of Mines accounted for 92% of crude helium production and 24% of high purity output. The remaining crude and high-purity helium was extracted by private industry.

[2] Output is piped to Cities Service Helex, Inc., plant at Ulysses, Kans. for purification.

[3] Purifies crude helium piped from Cities Service Cryogenics, Inc., plant at Scott City, Kans.

[4] Output is transported in highway semitrailers to other plants for purification.

Construction work was completed on a helium-enriching unit at the Bureau of Mines Exell plant during 1974. The work was accomplished under a contract with M. W. Kellogg Co. and its subcontractor, Control Automation. Principal work included piping and instrument calibration, pressure testing, and insulation of cold boxes. The enriching unit was tested and operational at yearend.

Several construction efforts were also completed or planned at the Bureau of Mines Keyes plant during 1974. Compressors at the plant were overhauled, and a new aluminum heat exchanger tube bundle was fabricated. In addition, a construction contract for helium trailer filling facilities at the Keyes plant was awarded to Hallmark Builders, Inc.

[4] Excludes return of conservation helium produced as indicated in footnote 2 to conservation storage system.

CONSUMPTION AND USES

Domestic consumption of helium during 1974 was primarily for purging and pressurizing rockets and spacecraft, research, welding, maintenance of controlled atmospheres, leak detection, and cryogenics. Demand occurred principally in the Pacific and Gulf Coast States.

Sales of high purity helium in the United States increased about 8% in 1974. However, Bureau of Mines helium sales, which accounted for 31% of domestic sales, decreased approximately 6% during the year owing to a decline in utilization for purging and pressurizing rockets and spacecraft.

Approximately 52% of Bureau of Mines sales in 1974 were made to Federal agencies, which are required by law to purchase all of their major helium requirements from the U.S. Department of the Interior. The Bureau of Mines f.o.b. plant price, which is set at $35 per thousand cubic feet for the purpose of financing the long-range helium conservation program, was not competitive with the 1974 average private f.o.b. plant price of $23 per thousand cubic feet.

Remaining Bureau sales in 1974 were through purchases by Federal agencies from private distributors under General Services Administration contracts, which required the distributors to purchase equivalent quantities from the Bureau of Mines. These contracts made relatively small quantities of helium readily available to Federal installations and reduced freight charges for small purchases. The proportion of Bureau helium sales distributed in this manner increased 10% in 1974.

All helium sold by the Bureau of Mines was shipped in gaseous form in cylinders, highway semitrailers, or railway tank cars. Private industry plants shipped helium in both gaseous and liquid form. Much of the helium transported in liquid form was delivered by semitrailers and containerized dewars to distribution centers, where most of the product was gasified and compressed into small cylinders and trailers for delivery to consumers.

[3] Most of this was purchased in bulk by commercial firms, repackaged in smaller containers, and then sold to Federal installations under contract arrangements with the General Services Administration.

CONSERVATION

Helium held in the Bureau of Mines conservation storage system, which includes the conservation pipeline network as well as the Cliffside gasfield near Amarillo, Tex. increased 1% during 1974. Of the 38,279 million cubic feet in storage, over 97% was held for the Bureau's conservation program. The remaining amount was stored under contract for private producers. All of the net addition to the helium conservation system was accounted for by deliveries from Bureau plants. Although one company (Cities Service Helex, Inc.) made some deliveries for its own future use, helium held for private producers own accounts decreased by 8.7% during the year.

The conservation storage system contains crude helium purchased by the Bureau of Mines under contracts entered into in 1961 and continued under court orders obtained during 1971 and early 1973 by Cities Service Helex, Inc., National Helium Corp., and Phillips Petroleum Company. As a result of the decision of the U.S. Court of Appeals for the Tenth Circuit in October, 1973 crude helium deliveries to the Bureau from Cities Service Helex, Inc., and National Helium Corp. ceased on November 12, 1973. However, Phillips Petroleum Co. opted to continue helium storage deliveries for its own account pending the outcome of negotiations on a long-term storage contract. These negotiations were unsuccessful and Phillips Petroleum Co. ceased deliveries for storage on December 12, 1973.

[2] Purified by the Bureau of Mines Keyes plant for the account of National Helium Corp.

RESOURCES

As of December 31, 1974, proved and probable helium resources in the United States were estimated to be 244.6 billion cubic feet. These resources include proved and probable helium reserves (in natural gas with a minimum helium content of 0.3%) estimated at 110.7 and 41.8 billion cubic feet, respectively. The remaining resource base includes 38.3 billion cubic feet of helium in the Bureau of Mines conservation storage system and 53.8 billion cubic feet of helium in proved gas reserves with a helium content of less than 0.3%.

A total of 88 gasfields in 10 States contain proved and probable helium reserves. The bulk of these reserves (about 90%) are in only five gasfields: The Tip Top field in Wyoming; the Hugoton field in Kansas, Oklahoma, and Texas; the Keyes field in Oklahoma; and the West Panhandle field and Cliffside field in Tex. Helium reserves in the Tip Top field were revised upward during 1974. Approximately 64% of the proved and probable reserves were in fields under production at yearend. Only about 9% of the helium-rich natural gas produced was processed for helium extraction, while helium in the remaining helium-rich gas output was wasted incidentally to the consumption of the gas.

Bureau of Mines efforts to identify new domestic and foreign helium resources continued during 1974. A total of 406 natural gas samples from 18 States and 5 foreign countries (Australia, Ethiopia, the Netherlands, Norway, and Taiwan) were collected and analyzed for helium content during the year. None of the samples indicated the presence of significant amounts of helium.

FOREIGN TRADE

High purity helium exports, all by private companies, increased approximately 7% in 1974 (compared with 9% in 1973). The exports comprised 32% of private industry sales and 24% of all high purity helium sales. Most of the exports were shipped to Western Europe.

[e] Estimate. [p] Preliminary.

WORLD REVIEW

The production of helium outside the United States totaled an estimated 140 million cubic feet in 1974. Canada produced about 35 million cubic feet from a plant in Saskatchewan, primarily for export to Japan and other Asian countries. A plant near Paris, France, produced about 10 million cubic feet of helium as a byproduct of nitrogen removal operations. The U.S.S.R. and other countries of Eastern Europe extracted an estimated 95 million cubic feet of helium during the year.

During 1974, plans were announced for a prototype helium extraction plant to be constructed in Alberta Province, Canada. The $300,000 plant is designed to recover 0.05% to 0.20% helium from natural gas by utilizing a diffusion process. Construction of the plant will be financed entirely by the Alberta government, but plant operations will be carried out by Alberta Helium, which is a new company composed of the provincial government, Trans Canada Pipelines, and Alberta Southern Gas. The plant is expected to process 2 million cubic feet of natural gas per day by 1977. Data obtained through plant operations will be used to determine the feasibility of a full-scale plant.

The construction of a nitrogen and helium extraction plant at Ostrow in southwestern Poland was nearing completion by yearend 1974. Petrocarbon Developments Ltd., a British firm, was building the plant under a contract with the Polish Government. When completed in 1975, the plant will process natural gas containing 45% nitrogen and 0.4% helium. The plant is expected to produce 150 million cubic feet of high purity helium per year.

Construction of the Republic of South Africa's first helium plant reportedly was completed in late 1974. The plant, located near Johannesburg, will extract helium from natural gas discovered in the Orange Free State goldfields.

TECHNOLOGY

During 1974, the world's first closed-cycle helium turbine was prepared for commissioning tests at a district heating plant in Oberhausen, West Germany. Although it will be operated as a commercial heating and electric power generation unit, the turbine is part of a long-range research program to develop a direct-cycle nuclear generating system employing a high-temperature gas-cooled reactor (HTGR). The Oberhausen project, a joint venture of West Germany industry and Government, will also provide the first mechanical life test of helium turbines functioning over a long period of time as part of an operational power station. Design and construction of the plant was the responsibility of G.H.H. Sterkrade and Kraftwerk Union.

General Atomic Co., jointly owned by Gulf Oil Corp. and the Royal Dutch-Shell Group, continued studies of helium gas turbines during 1974 for the Energy Research and Development Administration. The studies will assess the commercial feasibility of developing a helium-cooled nuclear reactor and employing the same helium in a closed cycle to drive the gas-turbine generator. This would eliminate the steam-turbine cycle ordinarily used in powerplants and allow heat rejection to take place directly to air in dry cooling towers, eliminating thermal pollution of streams and allowing utility companies more flexibility in picking powerplant sites. The gas turbines themselves could be located inside the same containment vessel that housed the reactor core, thus offering a capital cost savings.

During 1974, Air Products Ltd. (the United Kingdom) commissioned a cryogenic road tanker with a capacity of 11,000 U.S. gallons to carry liquid helium. The tanker reportedly is the largest of its kind in the world.

Iron Ore

By F. L. Klinger [1]

World production of iron ore in 1974 was estimated at 879 million tons,[2] about 5% more than in 1973. World exports increased about 8% to an estimated 395 million tons, of which about 82% was oceanborne. Imports of iron ore reported by the major consuming countries in 1974 included 140 million tons by Japan, 135 million tons by member countries of the European Coal and Steel Community (ECSC),[3] and 48 million tons by the United States. World consumption of iron ore probably increased in 1974; although consumption fell in some countries, including the United States and the United Kingdom, it rose in others, including Japan and West Germany. In general, demand for iron and steel was close to the 1973 levels.

World output of iron ore pellets was estimated at 157 million tons in 1974. While this was only about 5% more than in 1973, growth of production capacity over the longer term will continue to be relatively high because many new plants were under construction or planned. Worldwide, at least 80 million tons of new production capacity was expected to be installed by 1978. More than half of this capacity will be built in the United States and Brazil.

An increasing number of direct-reduction projects were evident in 1974, and growth in this sector appeared to be more rapid than the development of new pelletizing capacity. About 30 million tons of production capacity for sponge iron was expected to be installed worldwide by 1978. Installed capacity in 1974 amounted to about 5 million tons. The largest new projects were being located in countries having abundant domestic supplies of low-cost natural gas, such as Iran, Indonesia, and the U.S.S.R. Domestic reserves of iron ore were of secondary importance.

Iron ore prices rose significantly in 1974. Increases of up to 50% occurred in some countries, but the average increase in value of iron ore shipments was probably 15% to 25%. Further price increases were expected in 1975 as costs of production and fuels continued to rise. Railway and lake freight rates increased in the United States during 1974. Ocean freight rates, however, declined during the last half of the year as more vessels were diverted from the petroleum trade.

Vessel cargoes of more than 250,000 tons of iron ore were loaded in Brazil during 1974. The only port capable of receiving cargoes of this size appeared to be in Japan, although 200,000-ton cargoes could be accommodated at two ports in western Europe. The relatively shallow drafts available in U.S. ports continued to restrict the maximum size of incoming iron ore cargoes to about 65,000 tons. In the United States, several more 1,000-foot, self-unloading iron ore carriers were ordered for service on the Great Lakes.

The potentially high cost of environmental controls was illustrated in 1974 by a proposal of Reserve Mining Co., a major U.S. producer of iron ore pellets, to shift its tailings discharge from Lake Superior to an on-land site, add air pollution controls, and change its production process at an aggregate cost of $242 million.

---

[1] Physical scientist, Division of Ferrous Metals.

[2] Unless otherwise stated, the unit of weight used in this chapter is the long ton of 2,240 pounds.

[3] Excluding ore containing less than 42% iron, which is normally imported from France by Belgium, Luxembourg, and West Germany. Imports of French ore by the latter countries in 1974 totaled 16.8 million tons.

[3] Excludes byproduct ore.

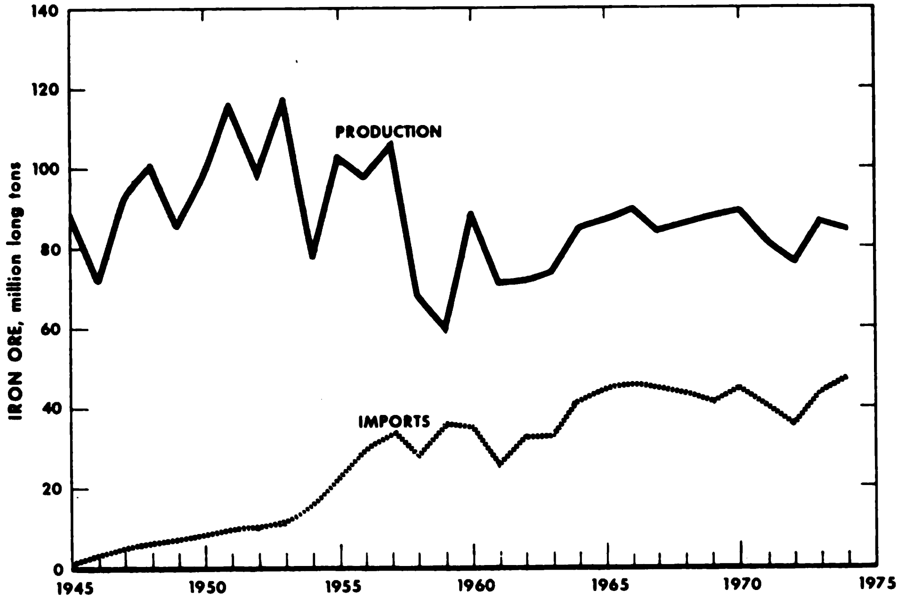

Figure 1.—United States iron ore production and imports for consumption.

EMPLOYMENT

Statistics on employment and productivity in the iron ore industry in 1973 and 1974 are shown in table 2. There was a slight decline in productivity in 1974, following a rise of about 8% in 1973. The decline was probably due in part to increasing employment at new mines and plants that did not begin production until relatively late in the year.

Employment data for 1973 and 1974

were collected by the Mining Enforcement and Safety Administration (MESA). As the number of shifts and average number of days worked were not reported, these data are not shown in table 2 as they were for 1972 and earlier years. The total number of hours worked were reported, however, so that continuity of data on hourly productivity was maintained.

Owing to changes in methods of reporting instituted by MESA or by some mining companies, the number of employees reported at some mining operations was considerably larger in 1973–74 than in 1972, but the total number of hours worked was not proportionately changed. Comparison of the average number of hours worked, per employee, for each year indicated abnormally high figures for 1972. Consequently, the total number of employees reported in industry for that year (14,000)[4] was probably at least 2,000 too low.

DOMESTIC PRODUCTION

U.S. mine production and shipments of iron ore in 1974 declined by 4% and 6%, respectively. Shipments of ore from U.S. ports on the Great Lakes totaled 68.8 million tons, about 7% less than 1973. Although the declines were mainly caused by lower demand, they were partly due to strikes at some mines during August and a 2-month strike by Canadian merchant marine officers which severely reduced shipments between the United States and Canada. The mine strikes occurred during the first 15 days of August, affecting a total of five companies and 10,000 employees in the Lake Superior district and reducing ore output by about 1.3 million tons. Domestic consumption of iron ore declined about 6%, and despite record imports the available supply at yearend was less than that 1 year earlier and was the lowest since 1956.

Mine output of usable ore consisted 72% of agglomerates, 22% of natural ore concentrates, and 6% of direct-shipping ore. Pellets made up 71% of total production. Increased output of direct-shipping ore in 1974 was largely due to production from the Stephens mine in Minnesota, which was inactive in 1973. The total number of active mines (66) was the same as in 1973 and included 60 open pits and 6 underground mines.

Crude ore production in 1974 was 217.2 million tons, only about 1% less than in 1973. Open-pit mines produced 96% of the total, and nearly 98% of the crude ore was shipped to beneficiation plants. The average iron content of all crude ore mined in 1974 was 33.7%, and the average for all usable ore produced was 60.6%. Nationwide, the ratio of crude ore mined to usable ore produced was 2.57:1, compared with 2.50:1 in 1972 and 1973.

The Lake Superior district accounted for about 84% of U.S. output of iron ore in 1974. Of the total production of usable ore, Minnesota produced 69% and Michigan 13%; the remaining 18% was produced in 19 other States.

In Minnesota, plans for four major taconite projects were announced during 1974, while construction of a fifth facility was continued. The five projects will increase annual production capacity for iron ore pellets on the Mesabi range by 21 million tons by 1978. Eveleth Taconite Co. will expand production capacity by 3.6 million tons (to a total of 6 million tons), Hanna Mining Co. will expand capacity of the National Steel Pellet Project by 3 million tons (to a total of 5.8 million tons), and United States Steel Corp. will expand capacity at Minntac by 6 million tons (to a total of 18.5 million tons). North of Virginia, Inland Steel Co. began construction of the Minorca facility, which will have a production capacity of 2.6 million tons of pellets per year. North of the Hull-Rust-Mahoning open pit, Hibbing Taconite Co. continued construction of its mine and plant which will have an initial production capacity of 5.4 million tons. The latter facility was scheduled to begin production in 1976, while the other four projects are slated for completion in 1977. Total investment in these projects was approximately $800 million. During 1974, production of iron ore pellets from the six taconite operations on the Mesabi range totaled 40.9 million tons.

The Whitney and Rana natural ore mines began production in 1974. The Whitney mine was operated by Hanna Mining Co. and the Rana mine by Rhude & Fryberger, Inc. The end product of both operations was natural ore concentrates. The

---

[4] Minerals Yearbook, V. I, 1972, p. 631.

Whitney ore was being processed at the Pierce concentrator, since the Pierce mine was closed by Hanna in early 1974. On the eastern Mesabi, United States Steel Corp. was preparing the Donora natural ore mine for production in 1975. The Donora mine is adjacent to the Stephens mine, from which United States Steel produced direct-shipping ore and concentrates in 1974. The Stephens mine was inactive in 1973. Ore reserves at the Donora property totaled about 10 million tons.

In the U.S. District Court in Minneapolis and St. Paul, trial of the suit brought against Reserve Mining Co. by the U.S. Department of Justice was concluded in 1974. The suit originally alleged that taconite tailings discharged by the company's concentrator at Silver Bay were polluting Lake Superior. Later, the Government also contended that fibrous particulate matter discharged into water and air constituted a public health hazard. The District Court ruled that there was a health hazard and ordered the plant closed on April 20. The plant resumed operations on April 22, after the U.S. Court of Appeals ruled that there was not enough evidence to support the District Court's decision. Later in the year, the company submitted a plan to State authorities by which it proposed to shift discharge of tailings to a basin on land, improve air quality controls, and modify its production process at a total cost of $242 million. By yearend, the plan had not been approved by the State agencies concerned.

In Michigan, the Tilden project south of Ishpeming was completed in 1974. The concentrator began production in October and the first shipment of pellets was made in December. The facility has a production capacity of 4 million tons of pellets per year and was built at a cost of $200 million. The concentrator is the first plant in the United States to beneficiate fine-grained, hematitic crude ore of the taconite type by cationic flotation of silica. The concentrating process is based on a method of flocculation and desliming patented by the Bureau of Mines. Another significant development was the expansion of production capacity at the Empire magnetic taconite facility by about 50%, to 5.2 million tons of pellets per year. Total production capacity for pellets in Michigan by yearend was 16.3 million tons per year. Production of pellets in 1974 was 10.7 million tons.

In Missouri, Pilot Knob Pellet Co., a subsidiary of the Hanna Mining Co., modified its plant to produce self-fluxing pellets. New installations included a flotation circuit to remove additional alkali and silica from the concentrate, and another secondary grinding mill. Production capacity was increased by 15% to 1.15 million tons of pellets per year. The crude ore feed for the plant is mined by underground methods and contains about 42% iron in the form of magnetite. Pellet shipments from Pilot Knob in 1974 totaled 683,000 tons.[5]

In Pennsylvania, Bethlehem Steel Corp. announced that the iron ore concentrator and pelletizing plant at Cornwall would be reactivated in early 1975. Ore for the plants will not be mined at Cornwall but will be purchased from other mines in the United States and abroad. The pellets will be shipped to the company's blast furnaces at Bethlehem and Johnstown, Pa. Production capacity for pellets will be about 750,000 tons per year.

CONSUMPTION

Consumption of iron ore and agglomerates in 1974 was about 6% less than in 1973. Consumption in steelmaking furnaces declined about 21%, while consumption in blast furnaces was down 5.8%. The decline in consumption for steelmaking appeared to be mainly related to the decline in output of open hearth steel and increased use of scrap for that purpose in 1974. Of the total consumption, blast furnaces accounted for 98.3%, steel furnaces accounted for 1.2%, and the remaining 0.5% was used in the manufacture of cement, heavy-media materials, and other miscellaneous products. In blast furnaces, the weight ratio of iron ore and agglomerates consumed to pig iron produced was 1.57:1 in 1974, compared with 1.56:1[6] in 1973.

Iron ore pellets made up 52% of all iron ore and agglomerates consumed, and 65.6% of all agglomerates consumed in

---

[5] Skillings' Mining Review. V. 64, No. 14, Apr. 5, 1975, p. 16.

[6] Revised figure.

1974. These proportions were almost identical to those of 1973.

Consumption data are shown in tables 11 and 12. In these tables, iron ore concentrate used to produce pellets and other agglomerates at mine sites is not reported as iron ore consumed; its consumption was reported only when such agglomerate was shipped to the furnace site and used (table 11). Iron ore concentrates and fines used to produce agglomerates (such as sinter) at iron and steelmaking plants is reported as iron ore consumed (table 12), and consumption of agglomerates from this source is included in table 11. In table 12 the difference in weight between iron ore consumed and agglomerate produced results from the addition of materials such as flue dust, mill scale, lime, and coke.

STOCKS

Stocks of iron ore and agglomerates at U.S. mines, docks, and consuming plants totaled 57.9 million tons on December 31, 1974. This was 3.3% less than a year earlier and the lowest since 1956. During 1974, stocks of ore at consuming plants were reduced to as little as 24 million tons, possibly a record low, and stock of ore at the mines at yearend totaled 9.4 million tons, the lowest since 1960. Of the 48.5 million tons on hand at U.S. docks and furnace yards at yearend, 62% consisted of U.S. ores, 15% of Canadian ores, and 23% of other foreign ores.

PRICES

Published prices for Lake Superior iron ores increased four times during 1974. The first increase was announced early in May, following increases in freight rates in March and April and the termination of price controls at the end of April. Subsequent increases came in June, following another rise in freight rates; in August, after negotiation of new labor contracts; and in late December. By yearend, published prices were 32% to 51% higher than at the beginning of the year. However, because the increases occurred at intervals of 1 to 4 months, and because the increase in December affected very little ore shipped during 1974, the average increase in price ranged from 17% to 20% for different grades.

The price changes and month of announcement are shown in the following tabulation:

1974 Month	Mesabi non-Bessemer (per long ton)	Mesabi Bessemer (per long ton)	Old Range non-Bessemer (per long ton)	Old Range Bessemer (per long ton)	Pellets (cents per long ton unit)
January	$11.91	$12.06	$12.16	$12.31	29.4–30.019
May	13.85	14.00	14.10	14.25	35.5
June	14.60	14.75	14.85	15.00	36.3
August	15.75	(1)	(1)	(1)	40.619
December [2]	17.28	(1)	(1)	(1)	44.559

[1] Not available at the times shown.

[2] Prices in effect for one company on Dec. 23. The pellet price was in effect for two companies on Dec. 30.

The increases were not the same for all companies, but the prices shown indicate the minimum and maximum values during 1974 for Mesabi non-bessemer ore and for iron ore pellets, the two principal grades of ore shipped from mines in the Lake Superior district. Except for pellets, the values represent the price per gross ton of ore, basis 51.5% Fe natural, delivered rail-of-vessel at lower lake ports. The price of pellets is shown in cents per long ton unit of contained iron, at the same delivery point. In all cases, any increase in transportation and handling costs, subsequent to the announcement date of the price shown, was to be borne by the buyer.

The average value (f.o.b. mine or concentrating plant) of usable iron ore shipped from domestic mines in 1974 was $16.34 per long ton, compared with $12.84

in 1973 and $12.20 in 1972. These values were calculated from producers' statements and approximated the commercial selling price less the cost of mine-to-market transportation.

Significant increases in price were also evident for many foreign iron ores in 1974. Contract prices for delivery of Swedish ores in 1974 were reported by the two major producers to be about 25% higher than in 1973. Prices for Liberian ores produced by the Lamco Joint Venture in 1974 averaged about 35% higher than in the previous year. The average f.o.b. value of Venezuelan iron ore exported to the United States, as indicated by data released by the Bureau of the Census, rose from $10.03 per long ton in January 1974 to $14.65 in December, an increase of 46%. The nominal price quoted in American Metal Market[7] for Brazilian iron ore (68% to 69% Fe, f.o.b. Atlantic shipping port) in mid-1974 was $15.00 per long ton, up 25% since late 1973. Elsewhere, price increases ranging between 15% and 30% were negotiated between Japanese buyers and various Australian, Canadian, Indian, and South American producers during 1974. Indications were also that ore prices would continue to rise in 1975.

TRANSPORTATION

The 1974 iron ore shipping season on the Great Lakes began at Escanaba, Mich., on April 1, and by April 18 ore shipments had started from the other six U.S. ports on the lakes. The resumption of shipping was only about 2 months after the last shipment of the 1973 season, which ended at Two Harbors, Minn., on February 5, 1974. Iron ore shipments during 1974 from U.S. lake ports totaled 68.8 million tons, about 7% less than in 1973; this total included 1.47 million tons shipped during the extended 1973 season through January and February 1974. An additional 18.8 million tons of ore was shipped during 1974 to destinations on the Great Lakes from Canadian ports, including Port Cartier, Pointe Noire, and Sept-Iles on the St. Lawrence River. Of the total lake shipments of 87.6 million tons, 75% consisted of iron ore pellets.

As in the past few years, the ore shipping season was extended past normal closing dates and shipments continued from six U.S. ports into 1975. The Welland Canal also stayed open about 1 month later than usual, until January 17, 1975. The latter extension was partly due to a backlog of ore and coal shipments to Canadian ports which resulted from a strike by Canadian mates and engineers lasting from August 8 to October 4, 1974.

Statistics on lake shipments of iron ore, by port, during the 1974 season (including shipments in early 1975) are shown in the following tabulation:

Lake shipping port	Number of vessels loaded[1]	Total tonnage shipped[2] (thousand long tons)	Average cargo (long tons)	Largest cargo (long tons)
Duluth, Minn	1,124	17,887	15,914	31,135
Taconite Harbor, Minn	423	11,014	26,038	58,274
Silver Bay, Minn	583	10,519	18,043	27,756
Two Harbors, Minn	444	10,379	23,376	54,169
Superior, Wis	528	10,150	19,223	30,837
Escanaba, Mich	549	9,106	16,586	32,620
Marquette, Mich	169	3,026	17,905	25,519
Total	3,830	72,081	XX	XX

XX Not applicable.

Source: Lake Carriers Association Annual Report 1974, p. 41, quoting U.S. Army Corps of Engineers, Waterborne Commerce of the United States, 1973, Part III.

The trend toward increasing size of lake ore carriers and automation of unloading systems continued. Three more 1,000-foot vessels of up to 59,000 tons cargo capacity were ordered during 1974, two by Bethlehem Steel Corp. and one by National Steel Corp. The Bethlehem vessels will be built by Bay Shipbuilding Corp. at Sturgeon Bay, Wis., and are scheduled to begin service in 1977 and 1979. The National Steel vessel will be built by American Ship Building Co. at Lorain, Ohio, and is scheduled to begin service in 1978. Construction of two similar vessels was begun by the latter company in 1974 for Pickands Mather & Co. Meanwhile, the 1,000-foot tug-barge unit *Presque Isle* completed its first year of service, carrying 37 cargoes averaging about 55,000 tons each of iron ore pellets from Two Harbors, Minn., to lower lake ports during the 1974 season. Two new ore carriers, of about 34,000- and 20,000-ton cargo capacity, began service in 1974; three vessels were converted to self-unloaders; and two vessels were lengthened by 120 feet each to increase cargo capacity. Lengthening of three more vessels and conversion of two others to self-unloaders was planned by 1976.

Litton Industries Inc. announced in mid-1974 that it was terminating operations and planning to sell its shipyard at Erie, Pa. The yard built the 1,000-foot carriers *Stewart J. Cort* and *Presque Isle.*

In ocean shipment of iron ore, individual cargoes of more than 220,000 tons were loaded for the first time at the Brazilian ports of Tubarão and Sepetiba during 1974. The largest cargo was 259,000 tons, loaded at Tubarão. These very large shipments were destined for Japan, where port facilities at the Oita iron and steelworks could accommodate vessels of up to 300,000 tons deadweight and four other works (Kimitsu, Tobata, Fukuyama, and Chiba) were reportedly capable of handling vessels of 200,000 deadweight tons or more. The largest cargo received in Europe in 1974 appeared to be about 156,000 tons, at Europoort, although reported capacities were 200,000 deadweight tons at Europoort and 250,000 deadweight tons at the Taranto steelworks in Italy. In Scotland, the British Steel Corp. began construction of a new iron ore receiving terminal at Hunterston on the Firth of Clyde; the facility was planned to accommodate vessels of up to 250,000 deadweight tons. In the United States, relatively shallow channel depths continued to limit incoming cargoes to about 65,000 tons.

Ocean freight rates for iron ore declined sharply during 1974. The decline appeared to be caused mainly by increased availability of combination (ore-oil or ore-bulk-oil) carriers, arising from a decline in petroleum trade. Spot fixtures reported by Metal Bulletin during 1974 indicated that many rates were 25% to 60% lower in December than in January. Some rates published during the fall of 1974 included the following (tonnage of cargo shown in parentheses): From Tubarão, Brazil, to Dunkirk and other West Europe, $4.10 to $6.25 per ton (72,000 to 80,000), and to Japan, $4.75 to $5.00 (125,000 to 135,000); from Sept-Iles, Canada, to U.S. east coast, $3.00 (35,000), to the Netherlands, $3.25 (70,000), and Immingham, England, $4.25 (78,000); from western Australia to West Europe, $5.80 to $7.50 (100,000 to 150,000), and to U.S. east coast, $8.20 (65,000); from Monrovia, Liberia, to West Europe, $3.55 to $5.50 (40,000 to 80,000); from Narvik to Teesside, United Kingdom (Redcar), $2.75 (75,000); from Peru to U.S. east coast, $8.50 (26,000); from Madras (India) to Dunkirk, $18.60 (38,000); and from Chile to Japan, $7.50 (100,000). The following tabulation shows various ore movements:

Ocean shipping port	Number of vessels loaded	Total tonnage shipped (thousand long tons)	Average cargo (long tons [1])	Largest cargo (long tons [1])
Tubarão, Brazil [2]	724	52,047	72,000	259,000

[e] Estimate. NA Not available.

[1] Rounded to nearest 1,000 tons.

[2] Exports only.

[3] Exports of Swedish ore.

[4] Including 303 tons destined for Great Lakes ports.

Principal source: Skillings' Mining Review, various issues, 1975.

Lake freight rates for iron ore were increased twice during 1974. The first increase was announced prior to the start of the 1974 shipping season, and the second was announced late in June. Rising fuel costs were cited as a major factor in both actions. There were no further increases by yearend; however, rates during the last half of the year were 25% to 34% higher than in December 1973. Rates in effect from late June through December 1974 were as follows, per gross ton: From the head of the lakes to lower lake ports, $3.30; from Marquette, Mich., to lower lake ports, $2.75; from Escanaba, Mich., to Detroit and Lake Erie, $2.48; and from Escanaba to lower Lake Michigan ports, $1.98. The additional charge for iron ore cargoes requiring more than 24 hours to unload, and for delivery to docks not capable of handling vessels of more than 23 feet draft, was increased to 25 cents per ton, from 10 cents in 1973. Handling charges (car to vessel at upper lake ports, and rail of vessel to car or stockpile at lower lake ports) ranged from 34 to 95 cent per ton and were about 24% higher than in 1973.

Railway freight rates during the last half of 1974 were mostly about 25% higher than in December 1973, although the increased cost for some hauls ranged between 8% and 37%. Rates published in December 1974[8] included the following:

	Per gross ton
Cuyuna and Mesabi Ranges to Duluth-Superior	$2.41
Menominee Range to Escanaba	2.24
Pellets from Empire mine to Presque Isle (Marquette)	1.10
Pellets from Nashwauk and Keewatin (Minn.) to Duluth-Superior, delivered direct into vessel	1.85
Pellets from Marquette Range to Escanaba, delivered into vessel	1.30
Mesabi Range to Chicago district	8.73
Mesabi Range to Pittsburgh and Wheeling districts	17.17
Black River Falls (Wis.) to Chicago	3.56
Lake Erie ports to Pittsburgh and Wheeling districts	4.51–4.62
Benson Mines (N.Y.) to Cleveland	8.11
Baltimore to Pittsburgh district	6.62
Pilot Knob, Mo., to Granite City, Ill.	3.43
Cedar City, Utah, to Minnequa, Colo.	11.25
Cima, Calif., to Los Angeles harbor	5.11

[8] Skillings' Mining Review. V. 63, No. 52, Dec. 28, 1974, p. 22.

FOREIGN TRADE

U.S. exports of iron ore in 1974 declined 15% in tonnage. The decline was mainly due to reduced deliveries to Canada, which resulted from a strike of Canadian merchant marine officers. The strike lasted from August 8 to October 4. Exports to Canada were 20% less than in 1973, and shipments to Japan were 4% less.

U.S. imports of iron ore for consumption reached an alltime high of 48 million tons in 1974. The total was 4% higher than the previous record of 46 million tons in 1966. Compared with 1973, imports from Canada declined by nearly 2 million tons, but this was more than made up by increased imports from Venezuela. Imports from Brazil increased by more than 100% to 6.6 million tons, and increases were evident from Angola, Australia, Chile, and Sweden. A total of 126,000 tons was also received from the Soviet Union. The Philadelphia and Baltimore customs districts continued to receive the bulk of incoming shipments, followed by Mobile, Cleveland, Buffalo, and Chicago, in that order.

The average value of imported iron ore, f.o.b. country of origin, was $14.50 per ton in 1974, compared with $12.32 in 1973. The average value of exported ore was $15.13 per ton, 10% higher than in 1973.

WORLD REVIEW

Australia.—With production of 95 million tons and exports of more than 80 million tons in 1974, Australia remained the world's second largest producer and leading exporter of iron ore. Company shipments in 1973 and 1974, in thousand long tons, were reported as follows:

Producer	1973	1974
Hamersley Iron Pty. Ltd	27,151	32,245
Mt. Newman Mining Co. Pty. Ltd	26,316	30,904
Goldsworthy Mining Ltd	8,469	7,931
Broken Hill Pty. Co. Ltd	11,928	10,925
Cliffs Robe River Iron Associates	8,333	10,887
Savage River Mines	2,334	2,340
Frances Creek Iron Mining Corp	800	486
Western Mining Corp. Ltd	835	578
Total	86,166	96,291

Source: Skillings' Mining Review, various issues, 1974 and 1975.

Prices for Australian iron ore under Japanese contracts were raised in September 1974 by 16% to 27%. Prices for most ore products appeared to be raised by $2.25 to $2.50 per ton.

In 1974, the Mt. Newman Co. increased production capacity for iron ore to 35 million tons annually. A further expansion of capacity to 40 million tons was underway by yearend.

Total shipments of iron ore pellets in 1974 were estimated at 9.5 million tons. Production of pellets by the Hamersley Co. was 1.6 million tons in 1974, 25% less than in 1973. The company was modifying its plant to increase production capacity to 3 million tons annually. Capacity of the Robe River pellet plant, from which 3.9 million tons was shipped in 1974, was being increased to 5 million tons per year.

Goldsworthy Mining Ltd. was planning to mine iron ore deposits in "Mining Area C," located in the Pilbara region about midway between Mount Whaleback and Mount Tom Price, by 1980. The deposits were reported to contain proved reserves of 750 million tons of ore averaging 62.5% iron and 0.06% phosphorus. Plans were to export 10 million tons of pellets and lump ore per year. Development projects would include a 264-mile railway and construction of a new loading pier at Port Hedland to accommodate 163,000 deadweight ton vessels. Cost of the project was estimated at about $500 million.

In July 1974 Western Mining Corp. Ltd. (WMC) completed contracted shipments of iron ore to Japan from the Koolanooka deposit, 132 miles southeast of Geraldton in western Australia. Operations were stopped because no additional contracts were negotiated. A joint venture owned 50% by WMC and 25% each by the Hanna Mining Co. and Homestake Mining Co., the mine had shipped 5.1 million tons of ore since early 1966.

Brazil.—Production and exports of iron ore continued to increase at a rapid rate. Exports in 1974 totaled about 58 million tons, 35% more than in 1973, and were valued at approximately $570 million. The principal destinations were the ECSC (23.4 million tons), Japan (19.1 million tons), and the United States (6 million tons).[9] Brazilian exports of iron ore in 1975 were expected to approach 70 million tons.

Production and exports of iron ore in 1974 by the major producers were as follows: Companhia Vale do Rio Doce (CVRD), 55 million tons of which 82% was exported; Minerações Brasileiras Reunidas, S.A. (MBR), 8.3 million tons of which 83% was exported; S.A. Mineração da Trindade, S.A. (SAMITRI) and Ferteco Mineração, S.A. (combined output), about 8 million tons of which 6.5 million tons were exported. Domestic shipments by all Brazilian producers totaled about 11 million tons.

Shipments of iron ore pellets in 1974 totaled 4.13 million tons, of which 79% was exported. All of the pellets were produced by CVRD in two plants at Tubarão. Under agreements announced in 1974 between CVRD and Italian, Japanese, Spanish, Egyptian, and West German companies, six more pelletizing plants with a total output capacity of 20 million tons will be built at Tubarão during the next 4 years. CVRD will have a 51% interest in most of these ventures. The first of these plants will come onstream in 1976, and three more will be completed in 1977. Under the agreement with the Egyptian company, 3.6 million tons of pellets are to be shipped annually to Egypt for reduction in a sponge iron plant to be built in Alexandria. CVRD will invest $4 million in the latter facility.

Amazonia Mineração S.A. (AMSA) continued engineering studies for exploitation of the Serra dos Carajas iron ore deposits in the State of Pará. Very large investments will be required (estimated at more than $2 billion) for mine development, construction of a 650-mile railroad, and port facilities near Itaqui, but the Government hoped that production of 12 million tons of ore annually could begin by 1980, reaching 50 million tons by 1985. Japanese, British, and Spanish companies were possible participants in the project. The mining concession was received by AMSA in 1974. AMSA was owned 51% by CVRD and 49% by United States Steel Corp.

Canada.—Exports of iron ore in 1974 totaled 36.7 million tons, of which about 55% was shipped to the United States, 30% to nations of the ECSC, and 12% to Japan. Imports were about 1 million tons less than in 1973, mainly because of a shipping strike on the Great Lakes. Consumption of iron ore in Canada was estimated at 13.4 million tons, compared with 13.5 million tons in 1973.[10]

The Quebec-Labrador region continued to account for the bulk of iron ore production, with 74% of the total in 1974, followed by Ontario (23%) and British Columbia (3%). The largest producers were Iron Ore Co. of Canada (IOC) with shipments of 20.3 million tons; Quebec Cartier Mining Co. (QCM), 8.3 million tons; and Wabush Mines, 5.75 million tons. Production by IOC was considerably less than expected, due to technical problems and high labor turnover. The company's output at Labrador City was 11.9 million tons, about half of expected capacity, while output from the new pelletizing plant at Sept-Iles was 1.9 million tons, about one-third of production capacity. The performance at both operations was much improved by yearend, and production in 1975 was expected to be substantially increased. Total output capacity of IOC was 33 million tons of iron ore products per year.

QCM continued to develop its properties at Mount Wright and Fire Lake for production in 1975. The 88-mile extension of the company's railroad, from Gagnon to Mount Wright, was completed in 1974, and construction of facilities at Mount Wright was reportedly 80% completed by yearend. Annual production capacity for concentrate will be 16 million tons at Mount Wright, and initially 1.2 million tons from the Fire Lake deposits, increasing to 5 million tons by 1977. In 1974 Sidbec-Dosco, Ltd., the Quebec-government-owned producer of iron and steel, announced that it will acquire 50% of the annual production from Fire Lake and has an option to acquire an additional 1.5 million tons per year. The company wants to build a pelletizing plant at Port Cartier, with an annual output capacity of 6 million tons. If the project is approved by the government, Sidbec-Dosco will provide $160 million for construction of the plant. Total cost of the project was estimated at $250 million. Sidbec-Dosco operated a 400,000-ton-per-year direct reduction plant at Contrecoeur in 1974 and ordered a second plant, with output capacity of 600,000 tons, for completion in 1976. Both plants employ the Midrex reduction process.

---

[9] According to 1974 import statistics published by the recipient countries.

[10] Goodman, R. J. Can. Min. J., v. 68, No. 754, February 1975, pp. 96–108.

At the Griffith mine in Ontario, the Steel Co. of Canada, Ltd. was building a direct-reduction plant of the Stelco-Lurgi/Republic-National (SL/RN) type. The plant will have a production capacity of about 400,000 tons of sponge iron per year and was scheduled for completion in 1975.

Steep Rock Iron Mines, Ltd. continued feasibility studies of its proposed iron ore concentrating, pelletizing, and direct-reduction project at Lake St. Joseph, Ontario. The project was estimated to cost about $500 million. Output capacity would be 4 million tons of pellets per year, half of which would be reduced to sponge iron.

Finland.—Rautaruukki Oy. continued to develop the Rautavaara underground iron ore mine in 1974. Production of iron concentrates was expected to begin in 1975 at the rate of 500,000 tons per year. The company also announced that the Mustavaara mine, now being developed for production in 1976, will supply 200,000 tons per year of pelletized iron concentrate. Output from both mines will be used at the company's blast furnaces near Raahe.

Finland's imports of iron ore in 1974 totaled 1.1 million tons.

Gabon, Guinea, and Ivory Coast.—In Gabon, the Government acquired 60% of Société des Mines de Fer de Mekambo (SOMIFER) in July 1974 for an undisclosed sum. The action was reportedly taken in the hope of speeding up development of the Belinga iron ore deposits. Bethlehem Steel Corp., one of the owners of SOMIFER, will conduct further field work and laboratory tests on the Belinga deposits during the next 2 years.

In Guinea, a technical and economic study of the Nimba iron ore deposits was undertaken in 1974 by the Swedish firm of Luossavaara-Kiirunavaara AB (LKAB). The study was directed toward an output of 15 million tons per year. The work was commissioned by Société des Mines de Fer de Guinée (Mifergui), which is 50% owned by the Government.

In Ivory Coast, a group of U.S., Japanese, and West European companies together with an Ivory Coast public corporation was studying the feasibility of exploiting the Mount Klahoyo iron deposits, near Man, by 1980. Annual production of 9 to 12 million tons of iron ore pellets was being considered, at a projected minimum cost of $450 million.

India.—Production and exports of iron ore in 1974 declined about 2% and 5%, respectively, compared with those in 1973. Exports were estimated at 20.4 million tons in 1974, with more than 80% destined for Japan.

Chowgule & Co. Ltd. planned to build a second iron ore pelletizing plant near Mormugao port in Goa. The new plant will have a production capacity of about 1.8 million tons per year and may be completed by 1977. The company produced about 450,000 tons of pellets in 1974 for export. Chowgule also contracted with a U.S. steel company in 1974 to supply 1 million tons of iron ore over a 4-year period.

The Government-owned Gujarat Industrial Investment Corporation Ltd. was reported to be planning construction of a direct-reduction plant for iron ore. The plant would have a production capacity of about 180,000 tons of sponge iron per year, would be fueled by natural gas from the Ramol oilfield in Gujarat, and would use iron ore produced in Goa or at the Hospet-Donamalai mines in Karnataka.

The proposed arrangement by which Iran would finance development of the Kudremukh iron ore deposits in return for exports of the ore to Iran apparently had not been formally concluded by the end of 1974.

Indonesia.—Iron ore production continued to be limited to concentration of beach sand deposits of titaniferous magnetite near Cilacap in central Java, by P. N. Aneka Tambang, a Government-owned company. Exports of concentrate in 1974 totaled about 370,000 tons, all of which was destined for Japan. The contract with the Japanese calls for export of 300,000 tons annually through fiscal 1980.

In west Java, Swindell-Dressler Co. of Pittsburgh, Pa., was building a direct-reduction plant for P. T. Krakatau-Ferrosteel. The facility will have a production capacity of 2 million tons of iron per year and will employ the reduction process developed by Hojalata y Lámina, S.A. (HYLSA) of Mexico. Completion of the project was planned by 1978.

A group of Japanese companies, assisted by the Indonesian Government, continued to study the feasibility of establishing an iron ore stockpiling and sintering center in southeastern Sumatra. Construction of facilities would start around 1980, and would include establishment of production capacity for 6 million tons of sinter per year. Later, this capacity would be doubled. Since most vessels carrying iron ore to Japan pass through this area, unloading in Sumatra instead of Japan would permit many vessels to pick up return cargoes such as petroleum without spending so much voyage time in ballast. It would also help to ease problems of land acquisition, labor costs, and pollution control at steel plants in Japan, and would provide larger stockpiles of ore than are now available to Japanese consumers.

Iran.—Iron ore continued to be produced at Bafq, near Yazd, for consumption at the iron and steelworks near Isfahan. Larger deposits at Gol-e-Gohar, south of Kerman, were being evaluated in 1974 by the Swedish firm of Gränges AB. Reserves of iron ore at Gol-e-Gohar were tentatively estimated by an Iranian source at 400 million tons. Proven reserves at Bafq were reported to be about 150 million tons. Exploitation of the Gol-e-Gohar deposits may require extension of the railroad from Zarand south to Kerman and Bandar Abbas, a project estimated to require 3 to 4 years for completion. The Iranian Government plans to make Bandar Abbas an important iron and steel center, using abundant supplies of natural gas to produce sponge iron from domestic and/or imported iron ore. In 1974 Swindell Dressler Co. of Pittsburgh, Pa., contracted with the National Iranian Steel Industries Co. (NISIC) for construction of a direct-reduction plant having a production capacity of 1 million tons of sponge iron per year. The plant was originally slated for construction at Isfahan but instead may be located at Bandar Abbas. The plant will employ the Hojalata y Lámina (HYL) reduction process and was scheduled for completion by 1977.

NISIC contracted with the West German firm of Thyssen A.G. in 1974 for construction of a reduction plant at Ahvaz. This plant will employ the Purofer reduction process and will have a production capacity of about 300,000 tons of sponge iron per year. Under a previous contract with Korf Industri und Handel G.m.b.H., a reduction plant using the Midrex process will also be built at Ahvaz. The latter facility will have a production capacity of 1.2 million tons of sponge iron per year; the first unit was scheduled to begin production in 1975. Another development in 1974 was a contract between NISIC and Lurgi Chemie und Huttentechnik of West Germany for construction of an iron ore pelletizing plant at Ahvaz. This plant will have a production capacity of 5 million tons of pellets per year and was scheduled for completion by 1978.

Iron ore for the Ahvaz plants was expected to be imported through the port of Bandar Shahpur at the northwest end of the Persian Gulf. Port facilities were being improved in 1974.

A proposed arrangement between the Iranian and Indian Governments, under which Iran would finance development of the Kudremukh iron deposits near the west coast of India in return for exports of iron ore to Iran, was apparently not yet concluded by yearend.

Japan.—Imports of iron ore in 1974 totaled 139.6 million tons valued at approximately $2 billion. Australia continued to be the major supplier with about 48% of the total, followed by Brazil (14%) and India (12%).

Production of iron ore agglomerates from imported and domestic ores totaled 115.1 million tons in 1974, including 108.6 million tons of sinter and 6.5 million tons of pellets. An additional 11.3 million tons of pellets was imported.

Consumption of iron-bearing materials by the Japanese iron and steel industry in 1974 included 115 million tons of conventional iron ore, 9.6 million tons of imported pellets, 4 million tons of titaniferous magnetite concentrates ("iron sands"), 1.5 million tons of ferruginous manganese ore, 100,000 tons of pyrite cinder, and 13.2 million tons of unspecified iron-bearing materials, probably furnace dust, slag, mill scale, etc.

Liberia.—Production and exports of iron ore increased slightly in 1974. Exports totaled 25.1 million tons, of which 18.2 million tons were destined for countries of the ECSC. Shipments of pellets by Bong Mining Co. and the Lamco Joint Venture totaled 4.2 million tons. Total ore shipments by producer, in million tons were: Lamco Joint Venture, 12.8; Bong, 6.7; National Iron Ore Co., 3.5; and Liberia Mining Co., 2.1.

Mauritania.—On November 28, 1974, the Mauritanian Government nationalized iron ore operations of S.A. des Mines de Fer de Mauritanie (MIFERMA). MIFERMA was principally owned by French interests, but British and Italian ownership was also significant; minor shares were also held by West German and U.S. groups, as well as by the Mauritanian Government. The state-owned company now controlling iron ore operations is Société Nationale Industrielle et Minière (SNIM). Iron ore exports, which totaled 11.5 million tons in 1974, account for about 40% of the country's gross national product and 60% of foreign exchange earnings.

Norway.—A/S Sydvaranger brought its second grate-kiln pelletizing plant into production at Kirkenes in May 1974. Production capacity for pellets was thus raised to 2.7 million tons per year. The company was also planning to build a direct-reduction plant for pellets on the island of Karmøy. Fuel for the plant would be natural gas from the Norwegian sector of the North Sea. The company applied to the Ministry of Industry for annual supplies of 12.4 billion cubic feet from the Frigg gasfield.

A/S Rana Gruber was preparing the Ortfjell ore body for production in 1976. This ore body contains about 150 million tons of ore averaging 32% iron, and will be the company's main source of ore by 1980.

Exports of iron ore from Norway in 1974 totaled 2.6 million tons.

South Africa, Republic of.—Production and exports of iron ore declined about 1% and 22%, respectively, compared with those of 1973. Exports totaled 2.65 million tons. Domestic consumption dropped slightly to 6.5 million tons. The South African Iron and Steel Industrial Corp. (ISCOR) continued to account for more than half of the country's output. The company shipped 3.8 million tons of ore from the Sishen mine and produced 2.1 million tons from the Thabazimbi mine during the year ended June 30, 1974. Palabora Mining Co. Ltd. produced 2.2 million tons of magnetite concentrate in 1974, down 28% from output in 1973.

ISCOR continued construction of mine, railway, and port facilities for the Sishen-Saldanha Bay project in 1974. Minable reserves of ore at Sishen were estimated at 1.34 billion tons containing 60% to 68% iron. The first port facilities at Saldanha Bay were scheduled for completion in 1976, at which time vessels of 100,000 deadweight tons can be handled. Later, berthing facilities will accommodate 250,000 deadweight ton vessels. Cost of the project was expected to exceed $1 billion, more than twice the cost estimated before construction began in 1973.

In 1974, Consolidated African Mines reported that contracts with Japanese buyers had been negotiated for the supply of about 8.5 million tons of manganiferous iron ore during the period 1977–86.

Sweden.—Production and exports of iron ore reached record levels in 1974. Production totaled 36.4 million tons, including 9 million tons of iron ore pellets, 16.8 million tons of direct-shipping ore, and 10.6 million tons of concentrate and natural ore fines. Exports totaled 32.6 million tons, including 7.4 million tons of pellets. Ore shipments, by port, in million tons, were:Narvik, 22.1; Lulea, 8.1; and Oxelösund, 1.5. The average price of Swedish ore products increased about 25% in 1974.

New plants for production of low-phosphorus iron ore concentrate at Grängesberg were expected to be brought onstream by Gränges AB in late 1976. Output of byproduct apatite concentrate was scheduled to increase to 170,000 tons per year. The new plants were estimated to cost $20 million.

United Kingdom.—Production of iron ore continued to decline. Output in 1974 was about half the quantity produced in 1973. One underground mine (the Llanharry in Glamorgan, Wales) was reportedly closed in 1974. Fourteen mines had been operated by divisions of the British Steel Corporation (BSC) in 1973; these included seven open pits in the Corby-Kettering area, operated by the Tubes Division, and seven mines operated by the General Steels Division including four open pits in the Scunthorpe area and three underground mines (Llanharry, in Glamorgan; Beckermet, in Cumberland; and Santon, near Scunthorpe).

Consumption of iron ore in the United Kingdom in 1974 totaled 22.4 million tons, including 18.5 million tons of imported ore and 3.9 million tons of domestically produced ore. The total consumption was 21.5% less than in 1973. Imports of iron ore in 1974 totaled 19.36 million tons, down 14% compared with 1973.

At the Redcar works, BSC's first iron ore pelletizing plant was scheduled for completion in 1975. The plant will employ the grate-kiln pelletizing system designed by the Allis-Chalmers Corp. of Milwaukee, Wis., and will have a production capacity of 3 million tons per year. BSC was also installing a new sinter plant and materials-handling system at the Redcar works, was constructing ore transfer facilities from Port Talbot to the Llanwern works in Wales, and began construction of a new iron ore terminal on the Firth of Clyde at Hunterston, Scotland. The Hunterston terminal will serve the Ravenscraig steelworks and will be capable of accommodating vessels of up to 250,000 deadweight tons. The corporation was also considering construction of a direct-reduction plant for iron ore pellets at Hunterston.

Venezuela.—The iron mining industry was nationalized by the Venezuelan Government, as of January 1, 1975. In December 1974, Iron Mines Co. of Venezuela (a subsidiary of Bethlehem Steel Corp.) and all capital assets of Orinoco Mining Co.[11] (a subsidiary of United States Steel Corp.) were sold to the Government. The Government agreed to sell substantial quantities of ore to both parent companies during the next 5 years.

Both production and exports appeared to set new records in 1974. Exports were estimated at 24 million tons, of which about 65% was destined for the United States. Production of prereduced iron ore (high-iron briquets) by Orinoco Mining Co. was 231,000 tons in 1974, about twice the quantity produced in 1973. Shipments of the briquets (225,000 tons) were apparently destined solely for Venezuelan consumers.

U.S.S.R.—Rising production and exports continued to be reported in Soviet statistics. Exports in 1974 totaled 42.6 million tons, of which 27% went to Czechoslovakia, 26% to Poland, 22% to Romania and Hungary, and 6% to East Germany. Japan, West Germany, and the United Kingdom reported imports of about 1 million tons each from the U.S.S.R. in 1974, and Italy reported imports of 1.65 million tons.

Production of iron ore pellets in 1974 was reported to be 22.9 million tons, about 9% more than in 1973. At least 8.7 million tons of new pelletizing capacity was under construction in 1974.

TECHNOLOGY

In mining equipment, trends toward increasing use of rotary drills for blast holes, larger capacity shovels, and haulage trucks were continued in 1974. Most taconite and natural ore pits on the Mesabi range and all taconite-type operations in Michigan were using rotary drills, although jet-piercer machines were still exclusively used in some taconite operations on the eastern Mesabi, such as at Eveleth Taconite Co. and Reserve Mining Co., and in certain types of iron formations in Michigan. The use of 15-inch-diameter bits was also increasing, and at least one large operation in Minnesota was experimenting with 17½-inch bits. Power shovels with 16-cubic-yard buckets will be used by Hibbing Taconite Co. A power shovel with a radically new front end, designed to make a horizontal pass or slice through the bank, was tested on the Mesabi range by Marion Power Shovel Co. during 1974. The new shovel was said to permit an increase in dipper capacity of up to 33% over conventional machines, and a significant gain in productivity was claimed.

The use of haulage trucks of 150-ton (170-short-ton) capacity was increasing worldwide, and several 180-ton (200-short-ton) units were reportedly shipped to Australia. Most trucks being used in Minnesota and Michigan open pit operations were of 85- to 120-ton capacity, although some 150-ton units were in use and will also be used by Hibbing Taconite Co. A 312-ton (350-short-ton) unit built by the Terex division of General Motors Corp. was being tested at the Eagle Mountain (California) mine of Kaiser Steel Corp. In materials handling, a conveyor system driven by radial tires was introduced by B. F. Goodrich Engineered Systems Co. and Continental Conveyor Co. The system was said to be extendable for miles and to permit the use of lighter weight belting and lower belt tensions, and to reduce the cost per ton of material moved.

---

[11] Except for the ore-reduction plant at Puerto Ordaz. This plant, which produces high-iron briquets, was sold to a company owned 51% by the Government and 49% by Orinoco Mining Co.

In milling of taconite, fully autogenous grinding was being used at the Empire and Tilden taconite concentrators in Michigan and will be used in the Hibbing Taconite Co. concentrator in Minnesota in 1976. Semi-autogenous grinding was being used in the Butler and National concentrators in Minnesota, with some shift to wet-grinding methods from the dry methods currently used.

In beneficiation of iron ore, the selective flocculation-desliming process patented by the Bureau of Mines was used prior to cationic flotation of silica in the Tilden concentrator started up by Cleveland-Cliffs Iron Co. in Michigan in late 1974. This was the first commercial plant to use this process for concentration of fine-grained hematitic ore of the taconite type. Application of the technique to beneficiation of nonmagnetic taconite on the Mesabi range was being investigated by the Bureau of Mines in 1974. Also being investigated was magnetizing roasting of the material, followed by magnetic separation and flotation, and high-intensity wet magnetic separation.

A high-intensity separator of the Carousel type was used in beneficiation tests on oxidized taconite on the Mesabi range in 1974, but results were not available. The separator had a processing capacity of 3 to 5 tons per hour and was built by Magnetic Engineering Associates, Inc. Twenty-six high-intensity separators of the Jones type were in commercial use at the Cauê plant of CVRD in Brazil.

The Bureau of Mines continued research on production of magnetic "superconcentrates," containing up to 70% iron and 2% or less of silica, from commercial magnetic concentrates produced at taconite plants in the Lake Superior region. In pilot plant tests, caustic scrubbing followed by flotation of silica produced superconcentrates containing 1.1% to 1.9% silica from commercial concentrates containing 4.2% to 7.0% silica, with iron recoveries of 90% to 93%, at reagent costs of about 33 cents per long ton of superconcentrates produced.[12] A cooperative research effort between the Bureau and Eveleth Taconite Co. was initiated in 1974 to produce superconcentrates containing less than 1.5% silica from plant concentrates containing about 4.5% silica. The project was undertaken because of high interest in the use of prereduced pellets for electric furnace steelmaking.

Expected shortages of natural gas and the rising cost of oil were causing intensive research on the use of pulverized solid fuels for induration of iron ore pellets. The Bureau of Mines was investigating the suitability of western subbituminous coal and lignite for this purpose, and the iron ore producing companies were believed to be testing bituminous coals. The need to evaluate substitute fuels was emphasized by reports that supplies of natural gas would not be adequate to accommodate the 21 million tons of new pellet production capacity expected to be installed in Minnesota by 1978.

The worldwide trend toward increasing production of iron ore pellets continued in 1974. New pellet plants or expansions of existing plants were completed or under construction in at least 10 countries. The United States remained in the forefront of this trend, with 62 million tons of production capacity during 1974, 68 million tons of capacity at yearend, and 21 million tons of new capacity scheduled for completion by 1978.

The Hanna Mining Co. was modifying its pellet plant at Pilot Knob, Mo., in 1974 to produce self-fluxing pellets. In Sweden, LKAB found that substitution of dolomite for limestone in the production of superfluxed pellets greatly reduced disintegration of the material during low-temperature (500° to 600°C) reduction. Such low-temperature conditions were said to be similar to those prevailing in the upper part of a blast furnace stack.[13] In other pellet research, the Bureau of Mines investigated the effect of adding manganese to iron ore pellets, in amounts ranging from 1% to 5%, as a substitute for the use of natural manganiferous ores.[14] Although addition of manganese dioxide or manganiferous iron ore caused no problems in the production of pellets, there was a reduction in reducibility of the product which indicated probable additional smelting expense. Bureau research on metallurgy of pelletized steel-furnace dusts showed that reduction roasting with carbon monoxide, high-carbon wastes, etc., achieved removal of most lead and zinc impurities while increasing the iron content of the pellets.[15]

There was a proliferation of projects for direct reduction of iron ore in 1974. New plants were under construction in the United States and at least 12 other countries, most of which had access to abundant supplies of natural gas. Some of these countries (such as Iran, Indonesia, and Saudi Arabia) had relatively little or no proved reserves of iron ore and expected to import that commodity. Most of the new plants will employ the Midrex or HYL reduction processes, although some installations using the Purofer, Fior, and SL/RN processes were being built. In late 1974, total production capacity of new plants under construction or ordered was about 14 million short tons of sponge iron per year with another 17 million tons planned by 1978.[16] Total capacity of plants operating by the end of 1974 was about 5 million tons annually.

e Estimate. p Preliminary. r Revised.

[1] In addition to the countries listed, Cuba and North Vietnam may produce iron ore, but definitive information on output, if any, is not available.

[2] Insofar as availability of sources permit, gross weight data in this table represent the nonduplicative sum of marketable iron ore, iron ore concentrates, and iron ore agglomerates produced by each of the listed countries. Moreover, concentrate and agglomerates produced from imported ores are excluded, under the assumption that the ore from which they are produced has been credited as marketable ore in the country where it was mined.

[3] Data represent actual reported weight of contained metal or are calculated from reported metal content. Estimated figures are based on latest available iron content reported except for the following countries, for which grades are U.S. Bureau of Mines estimates: Panama, Uruguay, Albania, Denmark, East Germany, Hungary, Southern Rhodesia, the People's Republic of China, and North Korea.

[4] Gross weight and metal content of shipments of usable iron ore, dry tons, including byproduct ore.

[5] Gross weight calculated from reported iron content based on a grade of 66.67% iron.

[6] Includes byproduct ore.

[7] Nickeliferous iron ore.

[8] Includes magnetite concentrate, pelletized iron oxide (from pyrite sinter) and roasted pyrite (purple ore).

[9] Includes "roasted ore," presumably pyrite sinter, not separable from available sources.

[10] Excludes iron oxide pellets produced from pyrite sinter.

[11] Includes manganiferous iron ore.

[12] Includes byproduct magnetite as follows in thousand long tons: 1972—2,952; 1973—2,068; 1974—2,148. Data erroneously listed in previous editions of this chapter as including manganiferous iron ore.

[13] Year beginning March 21 of that stated.

[14] Concentrates including concentrate derived from iron sand as follows in thousand long tons: 1972—539; 1973—274; 1974—128.

[15] Largely concentrates from magnetite-titanium sands.

Iron and Steel

By Horace T. Reno[1]

The iron and steel industry of the world produced slightly more steel in 1974 than it did in 1973, but in the last half of the year, output slacked off in European countries and in Japan. In the United States the industry operated at capacity through 10 months until slowed down by a labor strike in the coal mines. Steel plants in the Soviet Union operated at capacity throughout the year, and the U.S.S.R. regained the lead from the United States as the world's leading steel producer.

The steel industry of the United States produced 145.7 million tons of raw steel[2] ingots and castings, just 3% less than a record established in 1973. The industry shipped 109.5 million tons of steel mill products, 2% less than the 1973 record. Coking coal and electric power shortages plagued the industry throughout the year. The industry engaged in a concerted effort to conserve energy and continued its high rate of investment in equipment to control effluents damaging to the environment.

Domestic demand for iron and steel products exceeded supply throughout the year. The shortage of roof bolts, which was critical in 1973, was eased, but oil country goods continued in short supply. There was a shortage of bailing wire and of heavy plate for shipbuilding, industrial machinery, and other capital goods, and the Secretary of Agriculture asked the industry to increase its output of tinplate to prevent loss of food products.

According to the American Iron and Steel Institute (AISI), steel mill shipments of construction and contractors' products were 5% more than in 1973. Shipments to service centers and distributors were 2% more. Shipments to the machinery industry were about the same, but shipments to the automotive industry were 18% less in 1974 than in 1973. Exports of steel mill products were up 41%, while imports were up 7%.

---

[1] Physical scientist, Division of Ferrous Metals.

[2] The term raw steel, as used by the American Iron and Steel Institute, includes ingots, steel castings, and continuously cast steel. It corresponds to the term crude steel as used by the United Nations.

r Revised.

[1] American Iron and Steel Institute. Includes ingots, continuous cast steel, and all other cast forms.

[2] Based on average production in 1967 as 100.

[3] Data not comparable for all years.

PRODUCTION AND SHIPMENTS OF PIG IRON

Domestic production of pig iron totaled 95.5 million tons in 1974, a decrease of 5.8 million tons or 6% less than that produced in 1973. Average production of pig iron per blast-furnace-day decreased to 1,735.1 tons compared with 1,771.7 tons in 1973 and 1,789.6 tons in 1972 according to AISI. A total of 163 furnaces were in blast at the beginning of the year, including one that produced ferroalloys. At yearend the total number in blast had decreased to 136 with one producing ferroalloys. There were 204 producing blast furnaces at the beginning of the year, and 197 at yearend, of which 11 were being relined and 3 rebuilt.

Metalliferous Materials Consumed in Blast Furnaces.—For each ton of pig iron produced in 1974, an average of 1.665 tons of metalliferous materials was consumed in blast furnaces. Total net iron ore consumed in blast furnaces including agglomerates was 150.3 million short tons. The total tonnage of iron ore including manganiferous ore consumed by agglomerating plants at or near the blast furnaces in producing 40.9 million tons of agglomerates was 33.2 million tons. The remainder consisted of mill scale, coke, limestone, dolomite, and small amounts of other materials. Domestic pellets charged to the blast furnaces totaled 68.2 million tons, and sinter charged was 41.6 million tons. Pellets and other agglomerates from foreign sources added an additional 11.6 million tons.

Blast furnace oxygen consumption totaled 25.8 billion cubic feet according to AISI, compared with 21 billion cubic feet in 1973 and 15.5 billion cubic feet in 1972.

Data reported to the Bureau of Mines by the iron and steel industry showed that blast furnaces, through tuyere injection, consumed 16 billion cubic feet of natural gas, 4 billion cubic feet of coke oven gas, 239.6 million gallons of oil, 92.3 tons of tar, pitch, and miscellaneous fuels, and 213,583 tons of bituminous and 23,469 tons of anthracite coal in 1974.

PRODUCTION AND SHIPMENTS OF STEEL

The domestic steel industry produced 145.7 million tons of raw steel in 1974, 3% less than the record 151.0 million tons produced in 1973. The industry worked at practical capacity through the first three quarters of the year, but a labor strike in the coal mines and the need for long postponed maintenance cut back production in the last quarter. The 1974 steel index, based on production in 1967 as 100, was 114.5 compared with 118.5 in 1973 and 104.5 in 1972. Of the total, 56% was produced by the basic oxygen process (BOP), 24% by open-hearth furnaces and 20% by electric furnaces. Shipments of steel products for the year totaled 109.5 million tons, 2% less than the 111.4 million tons shipped in 1973. Shipments to the automotive market totaled 18.9 million tons, 18% less than in 1973, but shipments of oil country goods were up 21%, and shipments to the construction industry were up 4%.

Materials Used in Steelmaking.—Metallics charged to domestic steel furnaces in 1974, per ton of steel produced, averaged 1,240 pounds of pig iron, 1,143 pounds of scrap, and 25 pounds of iron ore, including agglomerates. In 1973, comparable quantities were 1,259 pounds of pig iron, 1,104 pounds of scrap, and 32 pounds of iron ore, including agglomerates.

According to AISI, steelmaking furnaces consumed 643,976 tons of fluorspar, 2.6 million tons of limestone, 7.9 million tons of lime, and 1.1 million tons of other fluxes. Oxygen consumption in steelmaking totaled the equivalent of 212.6 billion cubic feet compared with 215.1 billion cubic feet in 1973.

CONSUMPTION OF PIG IRON

Pig iron consumed in steelmaking totaled 93.1 million tons. Basic oxygen converters consumed 66.6 million tons; open hearths, 22.5 million tons; and electric furnaces, 1.2 million tons. An additional 2.8 million tons was consumed by iron foundries and miscellaneous users, primarily for charging cupola furnaces. Also, approximately 3.7 million tons in the form of molten metal was used in making ingot molds and direct castings.

PRICES

Throughout 1974 the prices of iron and steel products on world markets were above those in the United States for the first time since the steel industries were rebuilt in Europe and Japan after World War II. Price controls in the United States and the sellers' market throughout the world, resulted in an imbalance between foreign and domestic prices that ranged from $50 to $150 a ton through the first 4 months of the year. By yearend, however, the foreign prices for some grades of steel were equal to, or slightly above, prices for domestic steels.

In the United States steel mill products and pig iron were under strict price controls for the first 4 months of 1974. At the beginning of the year, most producers had petitions to raise prices pending before the Cost of Living Council. The Council allowed the steel companies to pass through scrap cost increases incurred after June 1, 1973, but postponed its ruling on a petition for a 5.3% price increase on heavy steel products until January 25. On that date the Council allowed companies with annual product sales of less than $50 million to raise prices on steel wire products, cold-rolled steel shapes, steel pipe, and electrometallurgical products, and allowed the major steel companies to increase prices on selected steel mill products from 2% to 9.5%, apparently depending on volume of the product and the complexity of the steelmaking processes involved.

On March 1 the Council ruled that domestic steel companies could raise prices on a wide range of steel products by 5% to 11% to enable the companies to recover on a dollar-for-dollar basis higher material and fuel costs incurred since November 1973. Accordingly, major steel producers increased product surcharges early in April by $50 to $78 per ton to pass through the higher scrap iron and steel prices.

Price controls on iron and steel, iron ore, and scrap iron were removed April 30. The major steel producers increased base prices for cold-rolled sheet by $20 a ton, hot-rolled sheet by $17.50 per ton, hot-rolled bars by $3.50 per ton, and carbon plate by $7 per ton. The industry continued to raise its prices selectively through May and June, but by the end of June prices had been stabilized and were relatively constant throughout the last half of the year.

The composite price for pig iron, according to Iron Age, began the year at $78.16 per short ton in January, increased to $81.12 a ton in March, was unchanged through May, but increased to $134.50 per ton in June, $155 per ton in July, to $170.56 per ton in November, and to $175.03 per ton in December. Effective December 27, 1974, the composite price for pig iron was raised to $180.50 per ton. The composite price for finished steel was $189.60 per ton at the beginning of the year, remained unchanged for the first 3 months, increased to approximately $200 a ton in April, $220 a ton in May and June, and was raised to $240.88 per ton in July. At yearend the composite price was $248.66 per ton.

FOREIGN TRADE

The worldwide steel industry boom which changed the pattern of U.S. foreign trade in steel in 1973 continued to affect it during the first part of 1974. Imports of steel mill products in the first 5 months of the year were the lowest since the first month of 1970. But, in the last half of the year imports increased, probably in anticipation of a strike by coal miners. By October imports reached 2.1 million net tons, the highest for 1 month since June 1971. Imports remained about 750,000 tons higher than the 1973 average through the remainder of the year. Imports for the entire year totaled 16,746,000 tons, 7% more than the quantity imported in 1973. Imports of carbon steel were 5% higher than in 1973, but imports of alloy steel were 5% less, while imports of stainless steel, 176,000 tons, were 38% more than the quantity imported in 1973. The European Community (EC) countries supplied 40% of the total, Japan 39%, Canada 8%, and other countries the remaining 13%.

The EC countries shipped 6,423,000 tons of steel to the United States, 2% less than in 1973. Imports of alloy steel from the Community were 4% less, but imports of stainless steel were 26% more than from the Community in 1973.

Japan supplied 6,158,000 tons, 9% more than in 1973, and 39% of the total of U.S. imports of steel. Although it supplied 35% of the alloy steel total, alloy steel imports from Japan were 14% less than those in 1969. Japan supplied 45% of the total of stainless steel imports into the United States, 65% more than in 1973.

Canada supplied only 8% of total iron and steel product imports, but 18% of the total imports of alloy steel, and 13% of the imports of stainless steel. Alloy steel imports were 42% higher than those from Canada in 1973, and stainless steel imports were 18% higher. Sweden supplied 10% of the total imports of alloy steel, 14% less than it supplied in 1973. It supplied 13% of the total imports of stainless steel, about the same quantity that it supplied in 1973.

Imports of iron and steel products in the United States in 1974 were valued at $5.6 billion, 83% more than in 1973. Iron and steel mill product exports were valued at $3.0 billion, nearly twice the value of 1973 exports. Thus, there was an unfavorable balance in steel mill trade of $2.6 billion.

WORLD REVIEW

NORTH AMERICA

Canada.—Canadian iron and steel companies continued their program of modernization and expansion. Among the significant works completed in 1974, the Steel Co. of Canada Ltd. (STELCO) completed a steel furnace plant at its Edmonton works, installed an 80-ton electric arc furnace at the McMaster works at Contrecoeur, and completed installation of a spiral weld tube mill at its Page-Hersey works near Welland, Ontario. The Sydney Steel Corp. (SYSCO) completed a rail-finishing mill, a 450-ton-per-day oxygen plant, installed a new hot blast stove, and rebuilt one blast furnace.

The Canadian industry operated at close to its practical capacity through most of the year. It produced 15 million tons of crude steel. Steel imports exceeded exports by approximately 1.4 million tons. Therefore, Canadian indicated crude steel equivalent consumption in 1974 was 16.4 million tons compared with the record 15.6 million tons in 1973.

STELCO announced plans to build a $2 billion steel mill on a 6,600-acre green field site between Port Dover and Nanticoke on the north shore of Lake Erie. The company started clearing the land to provide for the new plant.

After due investigation the U.S. Treasury Department found that pig iron from Canada was no longer being sold or was likely to be sold in the United States at less than fair value within the meaning of the Antidumping Act of 1921.

SOUTH AMERICA

Argentina.—The Argentine Government, in order to increase the Nation's steelmaking capacity, authorized formation of a corporation with majority State participation to construct and operate an integrated steel mill. An international tender was made for the selection of an associate company, but at yearend satisfactory responses had not yet been received.[8]

In view of the continued shortage of steel plate and billets in Argentina, the Government by Decree 1465, dated November 15, 1974, eliminated the duty on steel plate having a carbon content below 0.4% and on billets with under 0.25% of carbon content, but restricted imports to 250,000 tons of hot-rolled steel plates and 50,000 tons of cold-rolled plates. The regulations were valid through December 31, 1975.

Bolivia. — The Bolivian-Brazilian-Argentinian cooperative project to build an iron ore mining and iron and steel plant industrial complex based on the Mutún iron ore deposits, advanced significantly when Bolivia and Argentina agreed on an exchange of goods and raw materials from the project. Under the agreement, Argentina is to buy annually a minimum of 1.1 million short tons of iron ore concentrates or pellets, 992,070 short tons of sponge iron, 330,690 short tons of semifinished steel products, and 440,920 short tons of semifinished steel. Furthermore, Argentina is to finance Bolivian hydrocarbon exploration and exploitation in a yet undefined area. Bolivia is to supply Argentina with 282.5 million cubic feet per day of natural gas from presently known reserves for a period of 10 years. Furthermore, Bolivia is to supply the same quantity for 10 years from yet to be discovered natural gas deposits, after first fulfilling its own needs.[4]

Empresa Siderúrgica Boliviana S. A. (SIDERSA), the Bolivian-owned iron and steel concern, arranged for a $10 million loan from Brazil to finance feasibility studies on the Mutún project.[5]

Brazil.—Brazil continued to suffer from a serious steel shortage. Its steel imports in 1974 cost more than $1.5 billion, although the first program established by the National Steel Expansion Plan of 1970 was essentially completed by the beginning of the year. Therefore early in the year the Government, through the Conselho Consultivo da Industria Nacional de Siderúrgica (CONSIDER), revised its program as follows: (1) Expand Brazil's steelmaking capacity to 24 to 26 million tons at a cost of $6 billion; (2) accelerate expansions at the Cia. Siderúrgica Nacional (CSN), Usinas Siderúrgicas de Minas Gerais, S. A. (USIMINAS), and Cia. Siderúrgica Paulista (COSIPA); (3) form new steel companies; (4) reorganize the managerial and financial structure of the steel industry; and (5) promote foreign investment in the steel sector.[6]

Under this new program, Brazil is to become a net exporter of steel in the 1980's. SIDERBRAS S.A., the Government holding company, formed in 1973 to act as CONSIDER's investment and administrative agent, is to handle the financial arrangements under the program. It issued criteria for utilizing available credits, and it stipulated that all equipment purchases shall be made through international bidding in full compliance with the general rules of the World Bank and Inter-American Development Bank (IDB).

Among the new steel plants, work was started at the Tubarão complex, plans for which were announced in 1973, and planning was started for the Itaqui complex near the Port of São Luis, Maranhão. The Itaqui complex is to be coordinated with development of iron ore deposits at Carajas in the State of Pará.

The three large companies with existing steel plants, CSN, USIMINAS, and COSIPA, sent delegations to the United States, Europe, and Japan to discuss financing expansion equipment with foreign governments and international financial institutions. In December IDB approved loans of $63 million to CSN and $40 million to COSIPA, for 15 years at 8% annual interest.

Chile.—The iron and steel industry of Chile produced 700,000 short tons of steel ingots in 1974, 16% more than it produced in 1973. Compañía de Acero del Pacífico, S.A. (CAP), the State-owned vertically integrated company that produces more than 90% of Chile's iron and steel, renewed its capital investment program to expand its steel mill at Huachipato.[7] The Government of Chile approved limited expenditure of local currency for the CAP expansion project. The amount of local currency available limits the rate of expansion.

Colombia.—The Instituto Latinoamericano del Fierro y Acero (ILAFA) held its annual meeting in Bogotá in October. Most of the discussions at the conference were concerned with technology for using low-grade noncoking coal, which is abundant in Latin America. The major operating problems in the Latin American iron and steel industry in 1974 were caused by shortages of scrap metal and high-grade coal. These problems led conference participants to forecast increased use of direct reduction processes. Extended use of direct reduction would eliminate the scrap and coking coal problems; nevertheless, Colombia's only integrated steelmaker, Acerías Paz del Rio, S.A. planned to expand its operations with a blast furnace producing pig iron.[8]

EUROPE

It was a record year for the steel industries of Europe. Among those countries in the European Community, only the United Kingdom did not exceed its previous record. Among other Western European countries that produce more than a million tons of steel a year, only Norway did not establish a record. All Eastern European countries except Bulgaria made raw steel output records. The EC countries produced 172 million tons of steel, and other Western European countries produced 32 million tons. The Eastern European countries produced 204 million tons. Thus, the steel industry of Europe produced 408 million tons of steel, 4% more than the record established in 1973.

European Community (EC).—*France.*—The French iron and steel industry operated at practical capacity through the first half of the year and produced a record 29.8 million tons of raw steel in 1974, 7% more than in 1973. The first stage of construction of the iron and steel complex at Fos-sur-Mer was on schedule. Arrangements had not yet been made by yearend to finance the second stage of construction. Union Sidérurgique du Nord et de l'Est de la France S. A. (Usinor) reported that a group of steel producers have set up an organization to supply them with prereduced iron.[9]

Germany, West.—There was a strong increase in demand for West Germany's steel, but the domestic market was weak. Steelmakers increased their output 7% to 59 million tons compared with the 55 million produced in 1973. The trend to larger steel companies continued as Rheinstahl AG was merged into August Thyssen-Hütte A.G.[10]

Italy.—Italy's steel industry produced 26.2 million tons of raw steel in 1974, 13% more than it produced in 1973. Despite opposition from environmentalists, the Italian Interministerial Programming Committee (CIPE), approved construction of an iron and steel works at Gioia Tauro by ITALSIDER, S.p.A. Gioia Tauro will be Italy's fifth steelmaking center.[11]

United Kingdom.—The British steel industry started the year with its output restricted by a power shortage caused by labor trouble in the coal mines. The coal miners had refused to work overtime in the last 7 weeks of 1973 and struck February 9, 1974, after which steel output was cut back progressively in 10% increments to reach less than 50% of normal output before the strike was settled. In addition to the trouble caused by the coal strike, the industry continued to be plagued by wildcat walkouts in its own operations. British Steel Corp. (BSC) kept its plant at Llanwern closed until the unions there agreed to abandon wildcat walkouts.

The steel industry operated normally in the last half of the year, but its output of 24.7 million tons was down 16% from that of 1973. There was a severe shortage of steel in the United Kingdom throughout most of the year, although steel imports were up 40% from those of 1973 and exports were down 23%. Despite all its troubles, BSC reported profits of $125 million for the year, and its expansion projects were essentially on schedule. Construction was started on the corporation's first 5,000-ton-per-day blast furnace at Llanwern, and it was announced that a 10,000-ton-per-day furnace would be built for Redcar at Teesside.

This was the first full year that the United Kingdom had been a member of the EC, but the BSC was unable to take advantage of membership. The Government restricted exports and would not permit the BSC to raise its prices to those prevailing on the Continent. Furthermore, BSC's limited output did not provide sufficient steel for membership in the Community to make much difference in marketing. Nevertheless, the European Coal and Steel Community provided funds for British workers who lost their jobs because of BSC's new facilities.

BSC made formal arrangements for cooperative research with other steelmakers within the European Coal and Steel Community. Researchers at BSC explored possible uses for waste heat in steelworks, and studied ways to increase the flexibility of the energy supply. They studied the fragmentation of scrap at low temperature and the direct reduction of iron ore using natural gas. The European Nuclear Steelmaking Club (ENSEC), formed through BSC's initiative in 1973, had three working parties to determine the research and development needed for eventual application of nuclear heat to making steel.

[9] Iron and Steel Engineer, Annual Review. Developments in the Iron and Steel Industry During 1974. V. 52, No. 1, p. D-31.

[10] American Metal Market. Rheinstahl-Thyssen Merger is Approved. V. 81, No. 169, Aug. 29, 1974, p. 3.

[11] U.S. Bureau of Mines. Iron and Steel: Italy. Mineral Trade Notes, v. 71, No. 6, June 1974, pp. 8, 9.

Western Europe.—*Austria.*—The Austrian iron and steel industry produced a record 5.2 million tons of raw steel in 1974, 11% more than it produced in 1973. The nationalized steel combine, VÖEST-Alpine A.G., essentially completed its 5-year modernization and expansion program at the Linz plant. The program included modernization and extension of two existing blast furnaces, a third LD plant, enlargement of the existing sintering plant, a dust collection plant, an exhaust-cleaning system, a new continuous casting plant, a hydrochloric acid pickling plant, and an acid recovery system.[12]

Spain.—The Spanish steel industry produced a record 12.4 million tons of steel in 1974, 4% more than it produced in 1973. There was a high level of economic activity in 1974 throughout Spain.

The Spanish Government established a national iron and steel plan for the period 1974–82 by Decree 669, March 14, 1974. The plan anticipates steel consumption increasing from 11 million tons in 1974 to over 20 million tons in 1982. Under the plan, small, nonintegrated steel companies will be permitted to work together to increase their efficiency through joint research and marketing, and the program continues incentives and benefits that were provided under the decree of 1969.

Under the new plan selection and quality of iron and steel products will be standardized at the European level. Joint action will be permitted to achieve production specialization and commercialization in common and unified research. Costs will be allowed to be competitive at the international level, and iron and steel companies planning to increase their scrap consumption, as a result of installing electric furnaces, will be obligated to install sufficient prereduction facilities with capacity to substitute prereduced products for at least two-thirds of their total metallics consumption.

In order to obtain better geographic distribution in the Nation's steel industries under the plan, mini-mills are to be constructed at Campo de Gibraltar and in the major industrial zone of Galicia.[13] The new program offers benefits to producers of up to 40% to total fixed capital corresponding to new investments; compulsory land expropriation; and reduction of up to 95% of the general tax on property transfers, turnover taxes, custom duties, and compensatory tax levied on new capital goods and equipment not manufactured locally. The benefits are granted for a 5-year period and may be extended.

Eastern Europe.—The Council for Mutual Economic Assistance (CMEA), of the Permanent Commission for the Iron and Steel Industry, celebrated its 25th anniversary in 1974. The Permanent Commission was formed to foster Socialist economic integration of CMEA member countries, the U.S.S.R., Czechoslovakia, Romania, Poland, East Germany, Hungary, Bulgaria, and Cuba. Yugoslavia cooperates with the member countries. Member countries signed general agreements on comprehensive cooperation in construction of a plant in the U.S.S.R. for the production of ferruginous raw materials and various types of ferroalloys. The plant will enable the U.S.S.R. to supply member countries with these products over a long period of time.

The Permanent Commission was in the process of organizing scientific and technical cooperation among the CMEA member countries and Yugoslavia on conservation and improvement of the environment and on rational utilization of natural resources. In related actions CMEA established a computerized information center at its headquarters in Moscow. The center will consist of a computer complex and nine laboratories that will be connected with the scientific/technical information systems of all CMEA countries. One of its first projects will be to establish an international system for translation of industrial catalogs and establishment of an information data bank on agricultural machinery and tractor production. One of the principal functions will be to coordinate activities and prevent duplication of ferrous metallurgy research.

The CMEA countries and Yugoslavia agreed on scientific technical cooperation in direct recovery of iron from ore and established a coordinating center for the research in Romania.

U.S.S.R.—The U.S.S.R. displaced the United States as the world's leading steel producer, producing 149,914,000 tons of raw steel in 1974, exceeding their previous record of 1973 by 3%. The Russians claimed the world's largest blast furnace with a working volume of 5,000 cubic meters and a capacity of 4 million tons of iron per year at Krivoy Rog in the Ukraine. It supplants the previous largest furnace, in the U.S.S.R. at Lipetsk, which was lit in February 1973. According to reports the Krivoy Rog plant is highly automated with smelting controlled by computer. Raw materials are supplied to the furnace by two belt conveyors, each approximately 1,500 meters in length.[14]

---

[12] U.S. Embassy, Vienna, Austria. State Department Airgram A-95, Mar. 10, 1975, 3 pp.

[13] U.S. Embassy, Madrid, Spain. GOS Decree Establishes National Iron and Steel Plan. State Department Airgram A-90, Apr. 25, 1974, 3 pp.

The U.S.S.R. entered an agreement with a consortium of West German concerns, Salzgitter AG, Korf-Stahl AG, and Fried. Krupp Hüttenwerke AG, for the first stage of construction of a direct-reduction and associated steelworks plant in the Kursk Basin of Central U.S.S.R. The U.S.S.R. agreed to pay cash for the first stage, but Soviet officials made it clear that this method of financing does not set a precedent.[15]

AFRICA

Egypt, Arab Republic of.—The Egyptians produced 298,000 tons of raw steel in 1974, slightly more than they produced in 1973. Apparently the new facilities at the Helwan iron and steel complex being installed with the help of the U.S.S.R. did not operate during the year. Entrepreneurs from Japan, West Germany, and Brazil agreed to the construction of a sponge iron conversion plant in Alexandria. The Egyptian Government will participate in the company 50%, Japan 25%, West Germany 15%, and Brazil 10%. The project is to be capitalized at an estimated $150 million, of which as much as $80 million could be in U.S. goods and services.[16]

South Africa, Republic of.—The iron and steel industry of South Africa operated at capacity throughout 1974 to produce a record 6,356,000 tons of raw steel. The industry apparently was on the threshold of a major expansion program which could double its capacity by 1980. The principal problem seemed to be locating sufficient funds to finance the program.[17]

Representatives of employers and of 10 trade unions, representing about 70,000 white, colored, and Indian workers (plus the Chairman of Central Bantu Labor Board, speaking for about 280,000 unorganized blacks) negotiated a new industry-wide wage agreement in context of the National Industrial Council for Iron-Steel Engineering and Metallurgical Industry. The agreement raises the minimum wage for blacks from R64.00 to R78.00 per month ($94.14 to $114.74), and the minimum wage for artisans from R1.41 to R1.61 per hour ($2.07 to $2.37). The agreement was negotiated more than 6 months in advance of the time when the existing agreement was to expire.[18]

The Government-controlled South African Iron and Steel Industrial Corp. Ltd. (ISCOR) began producing steel at its new works at Newcastle early in March.[19] Highveld Steel and Vanadium Corp. Ltd. at Witbank was installing a four-strand caster for casting 100- to 140-millimeter billets.

ASIA

Most Asian countries except Japan and India produced more steel in 1974 than in 1973. In the aggregate they produced 175 million tons of raw steel in 1974 compared with 174 million tons produced in 1973.

China, People's Republic of.—China's steel industry produced a record 30 million tons of steel in 1974 but still fell far short of the potential demand. The Chinese negotiated with the Japanese and a consortium of 16 West German firms plus 1 Belgian firm and 1 Austrian firm to provide facilities for a hot and cold rolling mill at Whuhan.[20]

India.—The Indian iron and steel industry produced slightly less steel in 1974 than it did in 1973. The industry continued to be plagued by shortages of power, coke and coal, coke oven gas, and lack of coordinated planning. It was significant that although there was an acute shortage of steel in several different categories and India imported substantial quantities of high-value flat steel products, it exported low-value bars and rods. Most of the exports went to oil-producing Near Eastern countries. The Indian Government announced plans to export $125 million worth of iron and steel bars and rods during the 1974 fiscal year, April 1974 to March 1975.

[20] U.S. Consulate, Dusseldorf, West Germany. State Department Airgram A-34, Apr. 5, 1974, 1 p.

The first Linz Donawitz converter (BOF) at the Bokaro steel project in Bihar was formally inaugurated January 31, 1974. The new converter was the largest operated in India in 1974.[21]

Indonesia.—Swindell-Dressler Co., a division of Pullman, Inc., of the United States, announced that its contract with Ferrosteel A.G., a division of GHH of Essen, West Germany, to build an HyL direct reduction plant in Indonesia had been increased from $20 million to $80 million. The original contract was for a one-half-million-ton-per-year plant for P. T. Krakatau-Ferrosteel, at Kota Baja, West Java. The HyL plants will be part of a steel mill complex owned jointly by P. T. Krakatau and Ferrosteel A. G.[22]

Iran.—The Iranian Government continued actively to promote a domestic steel industry. Late in 1973, the Shah announced publicly a national goal of 15 million tons of steel production within 10 years. Contracts to build two more natural gas reduction plants brought the total commitment through 1974 to about 8 million tons of iron and steel capacity. A contract for construction of a million-ton-capacity gas reduction plant using the HyL process, was made with the Swindell-Dressler Corp. of the United States, and a contract for a 330,000-ton sponge plant using the Purofer method was signed with the Thyssen A.G. company of West Germany. The Purofer plant is to be at Ahwaz, site of the Korf Midland-Ross process plant, and the HyL plant may be built at Bandar-Abbas.[23]

Japan.—After more than 2 decades of unusual economic growth during which the gross national product rose at annual rates of up to 15%, the Japanese economy entered its most severe postwar slump. The Japanese steel industry was not as depressed as the overall economy, but it did not produce as much steel in 1974 as it did in 1973 despite exporting 36.5 million tons, 30% more than in 1973. The industry produced 129 million tons of steel; 115 million tons of the total was ordinary carbon steel and 14.5 million tons was special alloy steels; 104 million tons was produced in basic oxygen furnaces; 23 million tons in electric furnaces, and only 1.7 million tons in open hearths. Thus, basic oxygen furnaces (BOF) accounted for 81% of the total, electric furnaces 18%, and open hearth only 1%.

Japanese steel consumption, measured by domestic orders, totaled 68 million tons in 1974, 13% less than in 1973. The construction industry was the largest user with 60 million tons, 21% less than in 1973; the automobile industry used 7 million tons, 8% less than in 1973; and the shipbuilding industry used 8 million tons, 11% more than it used in 1973.

The Japanese Ministry of International Trade and Industry (MITI) assisted 23 steelmaking companies in forming a company to treat the dusts produced at their respective plants. The 23 companies discharge about 50,000 tons a year of recoverable dusts which contain 35% iron and 25% zinc.

The No. 5 blast furnace at the Fukuyama Works at Nippon Kokan KK produced a record 348,880 short tons of pig iron in April. The No. 5 furnace was lit in November 1973.

The experimental operations metallurgist of Nippon Kokan KK injected reducing gas directly into the stack of a blast furnace. Gas injection into the stack permitted equivalent reduction in blasts through the tuyeres, thereby permitting reduction in the size of blowers and hot stoves, as well as improving permeability in the melting zone.[24]

The Nuclear Steelmaking Technical Research Association started research on direct reduction processes in a shaft kiln at Hirohata Works of Nippon Steel Corp.[25]

OCEANIA

Australia.—The Australian steel industry produced 8.5 million tons of raw steel in 1974, slightly more than the 1973 record. Demand for steel continued strong throughout most of the year.

---

[25] Journal of Metals. Joint Study on the Direct Reduction Process To Be Instituted by the Steel Industry. V. 26, No. 1, January 1974, p. 4.

An international consortium of 13 private companies led by Australia's only steel producer, The Broken Hill Pty. Co. Ltd. (BHP), began a feasibility study to determine if it would be practical to build a large steel mill in Western Australia. Membership in the consortium was as follows: Australia: The Broken Hill Pty. Co. Ltd., and Pilbara Iron Ltd. (subsidiary of Colonial Sugar Refining Co. Ltd.); Japan: Nippon Steel Corp., Sumitomo Metal Mining Co. Ltd., Kawasaki Steel Corp., Kobe Steel Works, Ltd., and Nippon Kokan Co.; United States: AMAX, Inc., Jones & Laughlin Steel Corp., and National Steel Corp.; the United Kingdom: Guest Keen & Nettlefords, Limited, and British Steel Corp.; the Netherlands: Hoogovens IJmuiden Bv. A 10-million-ton semifinished steel plant was under consideration. Inasmuch as all members of the consortium are steel producers and/or users, the proposed plant could have an assured market.[26]

A joint Federal-State Government report entitled "The Pilbara Study" was released. The study was undertaken to determine if a steelworks, aluminum smelter, uranium enrichment plant, and a liquefied natural gas plant based on northwest shelf natural gas would be economically feasible.[27] The report contained 12 volumes of appendices and a 600-page summary. The summary was released to the public, but the 12 volumes of data were to be retained by the two governments for reference. Small, medium, and large industries in various combinations and/or complexes were considered. Estimated costs range from $4 million to more than $11 million. The report was not conclusive.

TECHNOLOGY

Most industrial research was designed to refine and perfect the new operating techniques and processes introduced in the last decade. Researchers looked for ways to improve continuous casting operations and oxygen steelmaking furnaces and ways to produce a wider variety of steels in the oxygen furnaces. There was the perennial search for better refining techniques and improved alloy steels, particularly the high-strength, low-alloy steels. A great deal of research was done on environmental controls, and studies were made on ways to use the variety of materials recovered from the effluents of steelmaking operations.

Conservation and development of new sources of energy was of great concern to the steel industry throughout the world. At the International Iron and Steel Institute's eighth annual conference, waste gas utilization, blast furnace fuel injection, coal gasification, and possible use of nuclear energy were among the subjects discussed.[28] An ad hoc working group on energy was formed to coordinate all activities relating to energy matters to avoid duplication and organize the work within a common framework.

The high cost of fuel oil and natural gas in some localities forced steel mills to discontinue use of these materials as blast furnace supplementary fuels. Substantial quantities of energy were saved by better housekeeping methods: Turning off lights, reducing the temperature in offices, cutting back on air-conditioning, and better maintenance of furnaces and steam lines.

Inland Steel Co. developed a linear programing model as a tool to obtain optimum use of energy at minimum cost at its Indiana Harbor works.[29] The model has been used to predict fuel and power requirements and costs for long-range plans involving major expansion projects in processing and finishing mills.

The No. 5 blast furnace at Fukuyama Works of Nippon Kokan in Japan, the world's largest blast furnace, produced 342,946 tons of hot metal in August, a record average of 11,063 tons per day.[30]

Top gas expansion turbine generators were installed at several blast furnace plants to conserve energy. This technique for conserving energy has been known for many years, but the capital expense of installing such equipment was not justified until the energy shortage more than doubled energy costs.

Development of direct reduction as a viable process for making steel accelerated in 1974. Bureau of Mines analysts counted 16 plants with a total annual capacity of 4,700,000 short tons operating profitably in midyear. Another 28 plants, with an estimated annual capacity of 12 million tons were in various stages of construction far enough advanced so that completion of all within the next 3 years was a practical certainty. Although seven direct reduction processes have been proved technically feasible and economically profitable in the last 5 years, they have not yet been operated for a long enough time in similar physical and economic environments to make a meaningful comparison of their merits. However, the existing high-iron briquet plant in Venezuela, and the planned Fior, Midrex, and HyL plants will facilitate comparison of the technical aspects of four processes, all of which were favorably regarded in 1974.

Bureau of Mines Research.—Bureau of Mines researchers at the Albany Metallurgy Research Center investigated the possibility of converting prereduced iron ore directly into homogenous workable steel with simple shapes. The objective of their work is to extend the usefulness of the electroslag melting process. This research also involves use of consumable electrodes of compacted prereduced iron ore pellets.

Bureau metallurgists at the Rolla Metallurgy Research Center continued their studies on developing methods for recovering valuable alloying metals from stainless, ferroalloy, and specialty steel wastes. The technical feasibility of recovering wastes such as flue dust, grinding swarf, and mill scale was demonstrated, and the economic feasibility of the processes was being investigated. Researchers at the Twin Cities Metallurgy Research Center continued studies on recovering and conserving thermal energy and increasing utilization of scrap in basic oxygen steelmaking operations. This project is entering the pilot plant stage to determine the technologic and economic parameters.

Table 2.—Pig iron produced and shipped in the United States, in 1974, by State

(Thousand short tons and thousand dollars)

State	Production	Shipped from furnaces		Average value per ton
		Quantity	Value	
Alabama	8,874	8,904	548,129	$140.40
Illinois	7,184	7,211	1,003,573	139.17
Indiana	17,001	17,022	1,991,438	116.99

r Revised. W Withheld to avoid disclosing individual company confidential data; included with "Total."

[1] Net ores and agglomerates equal ore plus agglomerates plus flue dust used minus flue dust recovered.

[2] Excludes home scrap produced at blast furnaces.

[3] Does not include recycled material.

[4] Fluxes consisted of the following: r 7,539 limestone, r 6,558 dolomite, and 471 other fluxes excluding 5,490 limestone, 3,437 dolomite, and 155 other fluxes used in agglomerating production at or near steel plants and an unknown quantity used in making agglomerates at mines.

[5] Fluxes consisted of the following: 6,763 limestone, 7,592 dolomite, and 520 other fluxes excluding 5,256 limestone, 15 burnt lime, 3,844 dolomite, and 288 other fluxes used in agglomerating production at or near steel plants and an unknown quantity used in making agglomerates at mines.

Table 7.—Steel production in the United States, by type of furnace[1]

(Thousand short tons)

Year	Open hearth[2]	Basic oxygen converter	Electric	Total

r Revised.
[1] Excludes molten pig iron used for ingot molds and direct castings.
[2] Included with "Other furnaces."
[3] Includes vacuum melting furnaces and miscellaneuos melting processes.

Table 10.—Consumption of pig iron[1] in the United States, by State
(Thousand short tons)

State	1974
Arkansas	8
Arizona	([2])
Connecticut	14
Delaware	([2])
